The feeds are prepared on lower floor, and after they are all prepared, are sent up to the shipping department by means of two electric elevators, and all day long the men wheel out truck load after truck load of Coulson's Egg Food and Coulson's Chick Foods—hundreds and hundreds of sacks, going to many different destinations—some going hundreds of miles south, some hundreds of miles north, some way east, and some across the water to the islands. Truly, it is a wonderful business, and it certainly must be a good feed. Coulson's Chick Feed, Coulson's Egg Food for Laying Hens, Coulson's Molting Food, etc.

Petaluma, California, known as the Egg Town or the White Leghorn City of the World; called so because of the millions of White Leghorn Chickens raised around there.

PETALUMA, CAL., is known as the greatest poultry center in the world. There are chickens by the million—nearly everybody for miles around is engaged in raising poultry. In taking a poultry census it was found that there was at one place, 35,000 laying hens in one square mile, and taking in a radius of 12 miles around Petaluma, there are about one million laying hens. There are many large poultry farms of 200 and 300 acres, and they will have from 3000 to 6000 laying hens, and they gather in eggs by the thousand.

There was shipped out from Petaluma, during the year 1903, 3,407,334 dozen eggs, and during the year 1904 three and a half million dozen, and, this does not include the millions of eggs that were placed in incubators, for there are hundreds and hundreds of poultry farms near Petaluma, and all have their incubators. Some have incubators to hatch out over 5000 chicks at a time, and on some places they will hatch out from 20,000 to 50,000 chicks, or more, each season.

To feed all these chickens it requires about 5000 tons of feed per month. This feed is brought in by railroads, boats and steamers. The Coulson Co. mix these feeds together, using certain proportions of each kind, so as to make a balanced ration, or proper feed for the fowls. The mixed feed for laying hens is put up in feed bags and is called COULSON'S EGG FOOD. Two kinds of feed is prepared for little chicks. The cheapest kind is made of ground grains and animal meals, and is called Coulson's Growing Chick Feed, and the best kind is COULSON'S SPECIAL Chick Feed, which is all granulated pieces of cracked grain, seeds, and tiny pieces of dried meats, granulated bone, etc.

The Coulson Co. is supplying the feed for these large and successful poultry farms, and, of course, it must be the best feed to produce such good results. Coulson's Poultry Food is now shipped to all parts of the Pacific Coast. Ask your feed dealer about it.

ANOTHER VIEW OF RETAIL DEPARTMENT OF COULSON'S POULTRY SUPPLY HOUSE.

Coulson's No. "3" Condition Powders for poultry—some for hens, some for little chicks, some for horses, some for stock of all kinds. Incubators, Lice Killers, Sprays, Disinfectants, Poultry Remedies, Roup Cure, Cholera Cure, Remedy for preventing little chicks from picking each other, etc.

If you want some good things to help your fowls, we can supply you. Send for our catalogue and let us hear how you are getting along with your poultry, chickens, turkeys, etc. Write to us now, while you think about it.

The home of Coulson's Poultry Food Co., showing exterior view of factory building on upper Main street, opposite the beautiful plaza.

Notice the big truck loads of Coulson's Egg Food and Coulson's Chick Food and also the hundreds of sacks piled up on the sidewalk ready for shipment and still more to come, for there are from 330 to over 400 sacks in a carload, and shipping 2 or 3 carloads in a day is common.

Feed your hens Coulson's Special Moulting Feed and you will have splendid success.

If you want to buy any feed, poultry supplies, incubators, condition powders, roup cure, lice killer, spray pumps, etc., send to Coulson Co. We can supply you at lowest prices.

Coulson Poultry and Stock Food Co., 730-732 Main Street Petaluma, California

Valuable Eucalypts for the Farmer

Many Profitable Varieties May be Crown in California and the Southwest. By Ernest Braunton.

We love to sing the praises of the great eucalypt family, for they serve us in a great variety of ways, overshadowing in importance the next three or four families in order of importance. To the people of tropic, semitropic, arid, or semi-arid districts they are what the bamboo is to the Japanese, except they furnish few food products. Extensively as they have been planted, they are not yet sufficiently appreciated, for in their native land the timber and other products of the eucalypt are put to a most surprising variety of uses. To the people of California they are most generally known as a quick-growing, drought-resistant tree only, but this is only one of the many important points in considering the tree, or family of trees, which has, in many districts, practically made life bearable on our treeless plains.

* * *

Eucalypts for Timber—With our rapidly increasing population, and as rapidly diminishing timber supply—a supply wholly insufficient from the first—we will ere many years be forced to plant timber trees, because of the almost prohibitory price of timber for general uses. In various parts of California the following list of valuable timber species may be grown—not all are adapted to all section: Botryoides, citriodora, corynocalyx, crebra, diversicolor, globulus, hemiphloia, leucoxylon, rostrata, rudis.

* * *

For Dry, Hot Sections.—Under semi-arid conditions we may grow four species very well: polyanthemos, rostrata, rudis, tereticornis. Of these polyanthemos is the best except that its growth is slow, although very hardy, and therefore safe to plant generally. E. rudis is nearly as hardy and drought resistant, a faster grower, a finer looking tree and far better adapted to general use. It makes a good street or shade tree. The other two mentioned are very close in appearance and much alike in every way; terticornis being the fastest in growth. Neither of them are as hardy, however, as the first two mentioned, but will do well in all parts of the south end of the State.

* * *

For Wet Soils.—Where water stands near the surface part of the year, no doubt botryoides and rostratra will do best; citriodora and globulus are not impatient of wet fet and crebra will stand some. Even that wonderful tree for arid sections, E. rudis, will thrive in quite moist soil—a jewel of adaptability.

* * *

Hardiness.—For cold situations, E. terecornis and leucoxylon are the best, perhaps the first is the hardier; it has been known to stand 15 degrees even when small. The following will probably stand more frost than the common blue gum: Corynocalyx, hemiphloia, melliodora, rostrata and rudis.

E. Rostrata.

Then comes a considerable number, such as: crebra, diversicolor, globulus, and viminalis. Most of these latter the writer has known to withstand 20 degrees and certainly all will safely pass through 24 degrees, even if occurring continuously for some time.

* * *

Windbreaks.—Aside from their uses as timber (firewood, fence posts, etc.) eucalypts are more generally planted for windbreaks and for such purpose surpass all other trees. Any of the species suited to your particular section may be used for this purpose, but on account of their rapid and satisfactory growth when thickly planted the common blue gum forms most of our windbreaks.

* * *

Ornament and Shade.—For narrow country roads, or city streets, the writer believes the scarlet flowering species (E. ficifolia) to be the best. This tree does not, however, thrive in case stunted, pot-bound plants are used. Such trees never regain their natural vigor. When well started this species makes a good sized tree of splendid shape, and when in bloom easily surpasses all others for oranmental purposes. Experience with street and ornamental trees is forcing the recognition of this beautiful eucalypt.

For country roads in general we have a fine, pink-flowering, silver-leaved variety of E. sideroxylon. This tree should occasionally be headed to make it umbrageous and also to keep the flowers where they may be seen.

E. leucoxylon makes an impressive tree for highway alignment; in age it is quite stately, quite striking in general appearance. Its tall, smooth-barked, white trunk makes one think of a polished marble column. This tree may be headed and made more widespread, is so desired.

E. polyanthemos is a round-leaved species, the most handsome foliage of all, silver-gray in color. Where well started, with occasional summer waterings for the first year, this tree has given excellent satisfaction.

E. calophylla is a tree quite similar in appearance to the E. robusta so extensively planted along streets in the past; but here the similarity ends, for calophylla is superior in all other respects. Some claim that robusta may be kept shapely if properly pruned, but it requires more pruning than any other species—its wood is the most brittle—it certainly is not the most ornate. Do not plant E. robusta.

In some locations, notably at Redlands, the narrow-leaved form of E. amygdalina gives splendid satisfaction and for country roadsides would suit wherever the climate will allow of its growth.

* * *

Oils, Perfumes, Etc.—Many tons of eucalyptus oil are each year extracted from the common blue gum in Southern California, and all druggists report an ever increasing sale of the oil and its by-products. We have several firms who manufacture upwards of ten tons of oil per year. Owing to the fact that the blue gum is the one most extensively planted, that species is the only one used in such factories, though it is said others contain more oil, particularly E. amygdalina. On the other hand, the red gum will not yield one-fourth the amount of oil obtained from the common blue. Other than oils there is manufactured eucalyptol, salve, soap, cough drops, perfumery, etc. For perfumery the best species seems to be E. Staigeriana, the lemon scented iron bark. Its foliage and twigs have a very heavy lemon smell. This trees is scarcely known in California at present. One hundred pounds of the dry

SILK IN SACRAMENTO.

S. R. Bellany, a young Swiss, who has spent a great part of his life among the silk producers of his native land, and understands all the details of the work, has been carrying on a line of experiments with silk worms in Sacramento and informs me that his success has been almost phenomenal. In Europe the growers always count upon a heavy precentage of loss. The worms die from various diseases, peculiar climatic conditions decimate them, and other causes reduce them greatly between the hatching and the spinning periods. In this case, there have been no losses, or they have been so light as not to be considered. The eggs he procured from Switzerland, receiving half an ounce in the shipment all of which hatched, and practically all attained maturity. Having no appliances for reeling the silk, the cocoons are of little use except to show what can be done in California with the silk worm. A large quantity of them has been sent to the Portland exhibit; masses of them are on display at the rooms of the Sacramento Chamber of Commerce and a very large exhibit is to be made at the State Fair. Certainly Mr. Bellany's experiment shows that silk can be produced here, and he states that it can be produced profitably if taken hold of in the right manner and by one who understands the business.

* * *

STATE FORESTRY BOARD.

The State Board of Forestry has been organized with Mr. E. T. Allen as State Forester, the board being composed of Governor Pardee, Secretary of State Curry and Attorney-General Webb. So far only preliminary work has been done. The vast destruction of our forests, by fires and vandal acts, has long made it evident that some action was required to put a stop to or control such destruction if we are to have any of our grand forests left to us. As population becomes denser the demand for lumber becomes greater, and at the same time danger from forest fires increase. It is largely to check this danger that the new board has been created, and full police powers have been given to arrest and punish any one transgressing its rules. It has power to appoint Fire Wardens in all the counties, whose duties will be to care for the districts for which they are appointed. These Fire Wardens have full police powers to arrest any one without warrant whom they have evidence of violating the forestry laws. Mr. Allen has already visited some of the State parks and forests and so soon as he can get the work of his office a little more in hand, he will commence the work of organization, and have the whole State properly officered before next spring. In this work he will visit all the forest sections of the State.

No part of the State will receive more benefit from this work than those which are dependent upon irrigation, for while there may be some doubt as to the influence of forests upon rainfall and climate, there can be none as to their value as conservators of moisture. A densely wooded country holds the rainfall and preserves the snow fall, giving it forth in springs and brooks all through the season, while in the same country denuded of its trees the rainfall drains off in a few hours after it has fallen and except at the time of actual precipitation, it is a dry, waterless waste. In the great work which Mr. Allen has now in hand he should have the hearty co-operation of every citizen nad be aided to the fullest extent by the supervisors of every county in which there are any forest trees.

* * *

IRRIGATION IN THE NORTHERN COUNTIES.

Two things are forcing upon the attention of the northern counties the advantages of, and we many say, the necessity for, irrigation. These are the gradual decline of wheat production and the increase of population. The former has made large holdings of unirrigated land unprofitable, and the latter has made a demand for small farms and diversified products. Diversified farming anywhere in California means irrigation. Outside of a comparatively limited area of naturally damp lands, no summer crop will grow here without the artificial application of water. In a country where we boast that we can rely upon fine weather any day for six or seven months in the year, it is unreasonable to expect that the ground will retain sufficient of the winter rainfall to carry through summer crops. It is true that in the so-called natural damp lands, summer crops—corn, potatoes, alfalfa, or vegetables may be grown without irrigation, but as a rule the great bulk of the land in the whole State is useless for such crops unless water can be applied and until this can be done these lands will remain worthless for any except the winter crops, such as can be grown during the rainy season and are out of the way before the dry season sets in. These are the grain crops—wheat, oats and barley, and it is no longer profitable to grow these, and is becoming less so year by year. This means irrigation as a necessity. Our vast wheat areas are too valuable to be abandoned, they comprise some of the best land in the State; they are no longer profitable for the only crop which can be grown upon them; it is neither feasible nor profitable to cultivate large bodies of land under irrigation. All of which means that these tracts will be cut up into small holdings and put under ditch. The work has already commenced, and more attention is being given to irrigation each season in Northern California. There is an unlimited water supply in this section and as population increases, as it is now doing with great rapidity, there will be a greater demand for farming lands—and farming lands with water. It is only a question of time when irrigation will be a matter of as great importance in the northern counties as it now is in the south.

* * *

Professor M. B. Waite, the pear blight expert of the Department of Agriculture, has returned from a trip through the orchards of the Sacramento valley and along the river and gives a very encouraging report of his observations. He states that the blight in the river orchards, the principal pear section of the State, is well in hand, and is not spreading. The effective work which was done there under the direction of the county horticultural commissioners last summer has evidently borne good results. The professor had singled out one large orchard at Marysville known as the Harkey orchard, and here Professor Smith of the University, with his assistants, have been operating during the summer, and Professor Waite says that it is practically free from the disease at the present time. The same is true of the Hawkins orchard at Anderson, another section taken for demonstrating work against the pear blight.

The professor left Sacramento last week for Chico, and thence up the Sacramento valley. From there he will visit the orchards in Oregon, Washington, and probably sections of Idaho, and then make his way back to Washington. He will return the beginning of November, with an assistant from the Department of Agriculture, and take up active work for the winter.

One of the features of the next Fruit Growers' convention to be held early in December, will be Professor Waite, who will give a practical talk, with illustrations, on pear blight and its control. He will have samples of blighted trees and show the method of cutting them and will also have a number of lantern slides showing the disease in different parts of the United States and illustrating the work that is being done against it.

It is our duty, if we can,

RACES OF HONEY-BEES.

The different races of bees that collect and store honey in hives are few in number, and are known under the following names: The German or black, the Ligurian or Italian; other varieties are known as the Cyprians, the Egyptians, the Syrians, and the Carniolians.

The Italians, it is supposed by some, originated from a cross between the black or German and the Egyptian bees, and probably some other race or races. Be this as it may, it is almost universially admitted that the Italians are, taking them all in all, superior at least to the black or German race. Of the Italians, there are the brown three-banded yellow, and the five-banded or golden varieties. Just which of the three kinds is best is a matter as yet undecided, though the brown or dark-colored Italians are thought by many to be the hardiest as well as the mildest tempered. While the five-banded are, in the estimation of some, thought to be quite as industrious workers as either of the other kinds, they are thought to be somewhat more inclined to swarm, which is not a desirable feature, as they are quite liable to cast so many swarms as to render them of little value for collecting and storing honey. A strong colony is always best for this purpose.

There are, I believe, some two or three different strains of the black bees. As to which is the best for honey-gathering, has, I think, never been a question of much concern. In addition to the foregoing varieties of bees, it may not be improper to state that in India and the Philippine Islands there are larger honey-bees than any of the kinds named above. But as to their general characteristics in the way of real worth, very little is at present known. I think Professeor Benton of the Entomological Department of Washington, has been assigned to the task of an effort to import them to this country, in order that their real worth may be fully tested. But no matter what kind of bees are kept, in order to insure success, it is a matter of the first importance for the bee-keeper to understand the habits of bees in order that their wants may be fully supplied.—Kansas Farmer.

HOW LONG DOES A BEE LIVE.

I was called upon the other day to decide this question. Two gentlemen, it appears, had an argument about the length of the life of the honey bee, and it seems that neither held the correct answer to this question. Of course, a bee's life varies. At some seasons twenty-six days is the limit of their life, at others six months, and very many die at twenty-one days. This applies only to the worker bees. Drones are shorter lived than workers, while the queen bee has been known to live to be six years old, yet this is an exception. Most queens are past their usefulness after the second season, but may be profitable to the owner as long as life lasts. The worker bees live only twenty-six days in the working or honey season. Bees hatched after the honey season is over live from one to six months, depending on the labor they have to perform. The exact age of the drone is not known for the bees often times kill them or force them from the hive when there is a scarcity of honey or after the swarming season. Yet there are cases on record where they have lived through the winter months.

The life of the queen bee depends to a great extent on the handling by the beekeeper. If you give a queen the opportunity of laying to her full capacity the first year of her life she will exert herself so that the next season her laying powers are not one-third of what they were the first year, and the bees are sure to discover this and proceed to raise for themselves another mother or queen. Any time that a queen begins to fail to keep up the population of the hive the bees start superceding cells, and sometimes the young queen will be found in the same hive laying along with the old one. This is an exception, but I have seen it many times. The laying powers vary with queen bees, some only laying a few hundred eggs daily, while a prolific queen will lay as high as 30,000 eggs daily under some conditions. Now, if bees did not die off at an early age it would take a very large hive to hold the bees hatched from the eggs of a good prolific queen. By taking note of this many beekeepers will easily see that the queen that only lays a few hundred eggs daily is not worth keeping, for it is easy to secure one that will produce many times this amount from any reliable queen breeder at a small cost. It pays to have the best, if they are only bees.—Pacific Homestead.

BEWARE OF IRON SULPHATE.

The Illinois Experiment Station has issued a circular warning farmers against the use of iron sulphate in building up soil fertility. From it we quote:

A large amount of advertising has been done by a company interested in the sale of iron and iron sulfate, and frequently copies of such advertising pamphlets are sent with the inquiry. This pamphlet entitled, "How to use Sulfate of Iron on the Farm," contains some very absurd and misleading statements, one of which is as follows:

"With from ten to fifteen pounds of sulfate of iron at a cost of 15 cents to 30 cents per ton of manure, you can produce a fertilizer equal in value to that which will cost you from $20 to $25 per ton."

As a matter of fact there is no conclusive evidence that such an addition of iron sulfate to farm manure would increase its value sufficient to pay the cost of the iron sulfate applied. Iron sulfate as a fertilizer or soil improver is not used in practical agriculture, and it is extremely doubtful if its use would be profitable under ordinary conditions. Practically all soils contain an abundance of iron and, if sulfur ever is lacking in a soil, it could be supplied much more economically in the form of calcium sulfate (gypsum or land plaster) than an iron sulfate. In some respects iron sulfate resembles calcium sulfate, both having power to absorb and retain ammonia when applied to farm manure, and both having a stimulating effect in the liberation of plant food from the soil.

The Kentucky Experiment Station reports an experiment in which sixty pounds of iron sulfate per acre were applied for corn and as a result sixty-eight bushels of corn per acre were produced. Where no iron sulfate was applied, seventy-three bushels of corn were produced.

After reviewing the history of experiments with iron sulfate as a fertilizer and conducting an extensive series of experiments themselves in water cultures, in artificial soils, and in natural soils, Boiret and Paturel, French investigators, have reached the following conclusions:

"Sulfate of iron is poisonous either in itself or on account of the acid which it sets free in passing to the state of basic ferric sulfate. It is used to advantage, therefore, only for producing certain secondary reactions (as a stimulant). In a calcerous soil, sulfate of iron transforms rapidly, giving sulfate of lime (gypsum) and oxide of iron. Almost any quantity of sulfate of iron may be applied without hindering growth to any considerable extent providing sufficient lime is present and planting is not done until several months after the amendment (stimulant) is incorporated in the soils. Sulfate of iron, like plaster (gypsum) acts principally in permitting the diffusion of potash, it may replace plaster for legumes and certain outer plants like requirements, such as potatoes, beets and grapes. Aside from these special cases, however, it is not believed that in practice anything is to be gained by adding this substance to formulas for manures."

As a matter of fact, gypsum, or land plaster, itself, acts almost entirely as a soil stimulant, and as a very general rule, the use of this plaster, or iron sulfate, or other plaster substitutes, as soil stimulants, should be avoided. If the soil is deficient in any essential element of plant food, it is much more profitable in the long run to increase the supply of the deficient plant food element itself, whether it be nitrogen, phosphorus or potassium, than it is to pay out money for soil stimulants which force the soil to give up more plant food than it otherwise would, and ultimately leave the land in a more impoverished condition than before the stimulant was applied.

Mrs. Nexdore—I've been thinking of having my daughter's voice cultivated. Would you? Mrs. Pepperey—By all means, if you have tried every other remedy.—Philadelphia Press.

The Duty of Water

By J. B. Neff, Anaheim, Cal.

The duty of water is usually defined as being the amount of water necessary to produce a crop, and varies according to the kind of crop and the soil, as well as the climatic conditions.

The unit of measure for reservoirs is the cubic foot, but this is too small for convenient use, and the acre foot—or quantity which will cover an acre one foot deep, is more generally used for large bodies of water. The term "acre foot" is to be preferred as it bears a direct relation to areas to be covered with the water. The time unit is usually one second, and flowing water is measured by "second feet" or the number of cubic feet passing a given point in one second of time. Measurement is frequently expressed in miners' inches, but a miner's inch is a variable quantity, though 50 miner's inches equals one "second foot" in California, and a constant flow of 50 miner's inches for 24 hours will equal two "acre feet." 100 miner's inches will cover one acre 2 inches deep in one hour.

Experiments have been made to determine the amount of water necessary to produce crops of different kinds. Among the most important of these are the experiments of Prof. King, of Wisconsin, who has found that it requires from 300 to 500 pounds of water to produce a pound of dry material. That is, that to produce a ton of hay it is necessary to have from 300 to 500 tons of water, which must be supplied by rain or irrigation. Enough water to cover an acre one inch deep will weigh about 113 tons, so that if one ton of hay is to be grown on an acre there must be from 3 to 5 inches of water applied at the proper time. The amount used is often largely in excess of this, as rains do not always come at the time nor in the quantity that will do the most good. The amount of water to be used varies with the kind of crop that is being grown; thus the water required to produce one cutting of alfalfa hay on one acre will be sufficient to produce a crop of corn on five acres. When it is considered that from four to six crops of alfalfa are taken from the same land every year it will be seen that a large supply of water must be at hand to grow alfalfa successfully. The quality of the soil being sandy loam and the climate being that of the southern coast counties, with 15 inches of rainfall, it may be said that corn will require, in rain and irrigating water, 20 inches to produce a crop, a walnut orchard with trees 12 to 18 years old will need 25 inches, an orange orchard in full bearing should have 30 inches and an alfalfa field will not do well on less than 60 inches for the season. The amount necessary on cultivated orchards will be greater or less in accordance with the amount of cultivation they receive; the better cultivation the less water will be needed.

Soils that are sandy will require more water, but where there is danger of leaching, the water should be applied in smaller quantities and oftener, while the heavier soils that are more retentive will need less water and it can be applied at longer intervals.

Very dry climates require more water and in some of the Arizona valleys where crops with shallow roots are grown, it is necessary to run water on the ground every eight to twelve days.

It is best to begin the season with the ground thoroughly wet and if the rainfall should be insufficient the irrigation should be done before the weather becomes hot, so as to avoid excessive evaporation. The depth of water required to soak the soil varies, but it has been found that one inch of water will saturate dry soil about three inches deep, though moisture will in a few days reach several inches farther and give the ground the appearance of being wet when it is very much below the point of saturation and would retain considerable additional moisture.

When the ground is first irrigated large quantities of water are sometimes needed to saturate and settle the subsoil. This settling of the subsoil is sometimes so great that it is necessary to go over the tract and regrade it. The writer remembers one particular tract which, when irrigated for the first time was so uneven that there were places where it was not possible to drive a buggy across.

The early irrigators used water wastefully in most cases, but as the country becomes more thickly settled and water becomes more valuable, better methods are brought into use and the duty of the water becomes much higher.

CENTRAL CANAL WORK.

The Glenn Transcript gives the following account of the work on the extension of Central canal, in the north central part of California:

"All is activity now along the line of the mammoth canal which will distribute water to thousands of acres of land in Glenn and Colusa counties. The beginning of the work marks the opening of an era of prosperity for this section of the Sacramento valley.

At the present time there are sixty men with thirty-eight four-horse teams working on the big ditch. Two camps have been started on the Glenn ranch where new work is being done. Three and a half miles of canal will be constructed to join the broken ends of the canal, the rights of way having been secured only recently. A third camp is located at St. John. The force of men and teams is being augmented daily and advertisements are out calling for two hundred more men.

Later on more men will be put to work. When the work is on in full blast, five hundred men will be on the payroll of the company.

Two immense graders, propelled by traction engines, will be started this week. Each one of these machines will do the work of a forty mule team and will hasten the completion of the work. They will move south on the canal. The surveying force is now about five miles out from town grading the old canal which must all be worked over, and some parts of it must necessarily be abandoned.

The contract for building the 800 foot crossing at Stony creek will be let at once and next week will see a force of carpenters and a pile driver at work there. This feat of engineering will cost the Canal Company $50,000.

The attorneys for the company say that the condemnation suit against the Herbert Kraft company in Tehama county, will be tried early next month, and as soon as a judgment is entered in the Superior Court, the new headgate and the new canal will be started. Three steam shovels will be used on this part of the work. They will be operated by two shifts, working day and night. At this rate the new part of the canal can be finished in about ninety days.

Next spring we will have water coursing down through the canal at least as far as Willows, if not down to Cortina creek in Colusa county. This system will be different from other irrigating systems in that water can be had every day in the year.

This means a green country all the year around and prosperity on every hand. From now on our county will grow, and the growth will be fast, for all that is needed to make our land as productive as any in the world is water, and this we are sure to have. In a few months Willows will be more deserving of the appellation of "Queen City of the Plains."

Salt should be eaten with nuts to aid digestion.

CITRUS FRUITS

By C. A. Day. Pasadena

EFFECT OF HEAT ON BLACK SCALE.

The hot weather of the last days of August have undoubtedly destroyed some of the young black scale, but it is not best to depend upon the heat to reduce the scale in numbers to a point where they will not require treatment. Nearer the coast, where there is a high degree of humidity in the atmosphere and low temperature, the scale seems to thrive better and are less liable to be affected by hot weather than in those inland districts with higher elevation, dry atmosphere and high temperature. The latter conditions are not favorable for black scale, and some years there is but a light stock of scale in the orchards of the higher foothills, especially on young, open-topped trees.

* * *

Injury from Spraying on Hot, Clear Days.—In last week's Cultivator we warned orchardists against spraying during extremely hot weather. An instance has just come to my notice where fruit and trees were injured by spraying during the late hot spell.

* * *

PURPLE SCALE.

The purple scale belongs to the armored group of scale insects and was brought to California from Florida on nursery stock in 1889. There are no effective parasites which attack it in this country. The scale covering of this insect is so tough and dense that it is impossible to destroy the eggs by any treatment that will not injure the tree. This insect attacks citrus trees exclusively, is a rapid breeder, practically continues to breed throughout the entire season, and when once an orchard is thoroughly infested it is a permanent fixture. It spreads slowly, as the young larvae only moves about for a short time after they are hatched out. This scale insect has gained a permanent foothold in at least three of the counties of Southern California.

Notwithstanding the strenuous efforts that have been made, the territory occupied by this scale has been enlarged from year to year. Purple scale not only is a draft on the tree but infests the fruit, in many cases to such a degree as to render it unfit for market. The expense of treatment is very much more than that of any other pest which infests citrus trees, requiring two or more treatments in a year to effectually control it. Spraying has not been a decided success and it requires two fumigations, twelve weeks apart, to catch the larvae of the different generations. Like red scale it requires from twenty-five to thirty-three per cent more cyanide than the black scale.

The infected fruit is a means of infection of new districts. Fruit peddlers who handle this fruit are a source of danger in carrying this scale from one section to another. The horticultural commission of Los Angeles county has held up and destroyed infected fruit in the hands of peddlers and fruit dealers in many of the towns and cities of Los Angeles county.

In one prominent citrus fruit growing district of Southern California the local horticultural inspector has in the past year discovered twenty infections of purple scale, many miles from any district known to be permanently infected with this scale. These infections in every case included two or three trees, and the work of disinfection has been thoroughly carried out with the object of exterminating the scale, which will be ultimately accomplished, even if the infected trees are destroyed.

But for the commission and its work of quarantine and disinfection there is no doubt but that the purple scale would before this time have seriously infected the whole citrus section, as this scale can be widely scattered by the means of infected fruit and nursery stock.

A PROFITABLE LEMON SEASON.

C. C. Teague, manager of the Limoneria grove at Santa Paula, stated to us the other day that his company had sold over forty cars of lemons this season at an average of $1600 per car f. o. b. The best price received for a single car was $2254 f. o. b. This car contained 312 boxes, one-third of which were seconds, which cut down the total about $75 from what it would have brought had the lemons all been first grade.

From ten to fifteen cars are now going out of the State daily, and this number will probably increase during the next few months, and while the prices may not rule as high as during the past few weeks, yet Mr. Teague thinks all lemons will bring a good profit for the balance of the year at least. Of course the high prices have taken every car out of the State that was cured, so that only lemons on the trees now can supply the market.

THE BROWN ROT.

Lemon growers will be rid of the brown rot by next season, if the experiments now being made prove as successful as they promise. For some time the State University has been carrying on a series of experiments at the Limoneria ranch, Santa Paula, under the direction of Prof. Smith, and the disease has been found to be of a virulent fungus character. Experiments have progressed far enough that it can be said a solution has been discovered, that can be made cheaply enough to be used in washing lemons, which will effectually kill all spores of the fungi, thus preventing its spread. This discovery will be of immense value to lemon growers, as it is estimated the losses this season from the brown rot will amount to $150,000.

FUNGUS FOR BLACK SCALE.

Dr. S. M. Woodbridge, of South Pasadena, is sending out the following circular to a few citrus growers, and asks the Cultivator to give it wider publicity. The Doctor does not claim for his fungus that he can eradicate the scale, but he believes he has something that will help.

"During the summer of 1898 I found on trees in San Bernardino county, some black scale (Lecanium oleae) that were evidently diseased. I brought samples of these scales to our laboratory in Los Angeles and had Prof. McClatchie make cultures of the fungus, which was apparently getting in its deadly work. Subsequently many cultures of this fungus were made and I distributed them widely through our scale infested districts. In some districts the work was quite effective that season. Mr. A. B. Smith, of San Dimas, had his ranch cleaned up by this fungus. In other places the disease seemed to make little headway. Believing that a disease is by far the cheapest method of getting rid of our scale pests, this department has persistently continued to make cultures annually, and has distributed them widely throughout Southern California. These have thrived, more or less indifferently, for a short time and then disappeared. This year the results were quite different and I find that this fungus disease has been doing very effective destruction in many localities, and it would appear to have become acclimated and I trust has come to stay, although it seems to have been "winter killed" for several successive years.

"The object of this communication is to get your assistance in the perpetuation and distribution of this fungus disease of the black scale.

"The fungus is grown in Petre dishes, i. e., cultures are made of it on pieces of sterilized bread about two inches square. When the cultures are made or at the proper time thereafter, three of them are mixed with a barrel of water at a temperature of not less than 70 degrees Fahrenheit. Such a barrel containing say 50 gallons of water, is enough to spray 1600 trees. I have done this by merely spraying, through an ordinary hand syringe, say one-half pint of the mixture on a tree, every fifth tree is enough to put the spray upon. Being a fungus and very light it is quickly distributed to its proper host and does effective work under proper conditions. Just what these favorable conditions are must be further determined and herein we need the growers' assistance.

"The fungus disease affects only, so far as has been observed, the young scale after hatching and before leaving the old shell, but if one of the brood is attacked all seem to get the disease and die. To detect the presence of the disease turn up an old scale and if a white fungus is found with the aid of a glass, on the edges of the scale and on the young ones, you will know the disease is present. Any one sending samples to me at South Pasadena, can have them examined and a culture returned to him after the winter rains are over. The cost of perpetuation and distribution of this disease is merely nominal on an acreage basis.—S. M. Woodbridge.

SOME BIG LEMON PRICES.

The Southern California Fruit Exchange furnishes the following figures of banner sales of lemons during the year ending August 31, 1905:

	Total Boxes	F'cy	Ch.	St'd	Net Amt. Recd F.O.B.
One Car	312		229	83	$2252
do	312	40	239	33	2232
do	312	238	63	6	2217
do	312	27	257	28	2151
do	312	184	116	12	2078
do	312	201	91	20	2067
do	312	226	60	7	2048
do	312		253	59	2031
do	312		312		2006
do	312	141	131	40	2000
do	312		251	61	2141

Also:

12 cars	Lemons	that	netted	bet.	$1900 and $2000
13 "	"	"	"	"	1800 and 1900
13 "	"	"	"	"	1700 and 1800
19 "	"	"	"	"	1600 and 1700
21 "	"	"	"	"	1500 and 1600
28 "	"	"	"	"	1400 and 1500
46 "	"	"	"	"	1300 and 1400
46 "	"	"	"	"	1200 and 1300
49 "	"	"	"	"	1100 and 1200
58 "	"	"	"	"	1000 and 1100

The first car noted above, which brought $2252, was for C. D. Hubbard, of San Fernando, and gets close to the price we quote in another place, received by the Limoneira Company.

The above record for last year is not complete, for the reason that on quite a bunch of cars shipped prior to September 1st, report of sale has not been received.

BY ERNEST BRAUNTON, LOS ANGELES, CAL.

SEPTEMBER VEGETABLE CALENDAR.

A few more sorts of vegetables may be planted in September than was advisable during August. The hottest weather is now past, and we must begin to look forward to winter crops. The following may be planted: Beets, beans, cabbage (seeds or plants of early sorts), carrot, cauliflower, (seeds or plants,) kale, kohl rabi, lettuce, onion, parsnip, peas, radish, spinach, turnip.

THE CAROLINA JESSAMINE.

This native climber is not appreciated in California as it should be. If planted in whole or partial shade it does very well, but in the open our summers prove too dry for it. The flowers are in large clusters and of very bright yellow, extremely fragrant and contrast finely with the smooth, shining leaves. It is native from Virginia to Florida and a southern nurseryman says of it: "Not cultivated to the extent it desrves. Will grow on any land, rich or poor, wet or dry. Quick growing and for several weeks in spring literally covered with its lovely, fragrant yellow flowers."

Its catalogue name is Gelsemium sempervirens.

GARDEN NOTES.

Plant some freesias, and the earlier they are planted the better. They are easy to grow, and their flowers are exqusitely fragrant.

Seed-saving is one of the most fascinating of the gardener's occupations, but if many blossoms are left they lessen the plant's vitality and shorten its period of bloom.

Plants raised in beds, baskets, vases and window boxes need twice as much water as plants grown elsewhere. Soak them thoroughly in dry weather.

A new lawn can be kept in much finer condition if the grass is cut so often that it will not need raking. The clippings will serve as a mulch to protect the roots from the hot sun.

Plant choice petunia seed this month and have some blooming plants for your winter garden. A few petunias will keep a garden filled with beauty all winter.

A good many plants are better and stronger this dry weather if they are given a little mulch, which will help retain the soil moisture. Mulch your sweet peas and lillies.

Perennial seedlings may be started during September for next year's blooming, and they will do quite as well, and many varieties even better, than when started into growth early in the spring with the annuals.

If chrysanthemums are troubled with small black ants or other insects try spriukling them with tobacco tea or tobacco dust. The insects may thus be destroyed before the flowers bloom.

If old pansy plants are cut back, almost to the roots about the middle of September, when the hot dry season is over, the plants send up the growth which bears fine large flowers, if the soil has ben enriched. The bed that has been supplying quantities of flowers throughout the spring and summer should have all fading flowers picked off, and a liberal top dressing of manure. It will soon show renewed vigor and beauty. In the late autumn better set out new, young plants.

INFLUENCE OF NURSERYMEN.

The nurseryman, the manufacturer of nursery stock, like the manufacturer of boots and shoes, hats and clothing, shapes the fashion of the day. In this regard they carry a heavy responseibility, they can shape public demand to a remarkable degree. For instance, thousands, perhaps millions of quick-growing, short-lived, imported trees that are only fitted for temporary effects, have been sold for street trees, boulevards and parks. It is true that the tree has its place, may be used for quick effects, for a filler between slower growing, permanent trees, but too often it is set out as a finality. This is but one of the striking instances where the nurseryman can do much to mold public opinion along right lines bearing upon public utility and public beauty.

Along the line of esthetics in planting, how many lawns have been rendered unsightly by the planting of vegetable monstrosities in the form of cheap and distinctly ugly weeping trees. Perhaps the weeping willow is the most obstrusively objectionable; it is omnipresent in the smaller towns. Among the more permanent and desirable forms are the drooping beeches and elms, but even these can be over done, especially in a land of evergreens like our State. Nurserymen should not yield to the demand for quick results and propagate for sale cheap, short-lived shade trees, but should use their influence in molding public taste in the matter of lawn and street planting so that trees shall be set more for their intrinsic qualities of beauty and endurance, rather than from the standpoint of the incongruous and curious.

A pinch of soda in the water will keep the flowers fresh much longer than ordinarily.

The Carolina Jessamine.

IMMUNITY FROM FUNGI.

An Australian agricultural station has lately made some interesting experiments to render immune from parasitic fungi plants of tomato and cucumber. Three hundred cucumber seedlings and an equal number of tomato seedlings were subjected to experiment, fifty of each being used as check plants. When the seedlings were a fortnight old, the cucumbers were grouped round eight large cucumber plants badly affected by authracnose and "wilt." and the tomato seedlings were ranged about tomato plants bearing numerous blotches on the leaves, caused by "leaf blight." The specific course of treatment consisted of watering the plants every third day with a solution consisting of 1 part of sulphate of copper in 7000 part of water. The check plants, which were not watered with the copper solution, were indiscriminately mixed with the treated plants. The watering was done during the afternoon, and the quantity used for each plant was sufficient to soak the soil thoroughly.

After a month, all the treated tomato plants were perfectly free from disease. On the other hand, one or both cotyledons of thirty-four cucumber plants showed blotches of the disease. At the same time a considerable number of untreated check plants, both cucumbers and tomatoes, were badly diseased. At this stage, both treated plants and checks were sprayed with water containing the spores causing their respective diseases, and this was continued weekly until the end of the experiments. Under this drastic treatment, all the untreated check plants, both cucumbers and tomatoes, were badly diseased during the following two weeks.

After six weeks' treatment the strength of the solution was increased to 1 part of solution of copper in 6000 parts of water, and the soil in which the plants were growing was soaked every fourth day until the end of the experiments, which lasted for eleven weeks. At the expiration of this period, both cucumber and tomato plants were bearing a good crop of well-grown mature fruit.

Not a single one of the tomato plants treated with the sulphate of copper solution showed a trace of disease, and in the case of the treated cucumber plants the disease never extended beyound the cotyledons (elementary leaves) and this, notwithstanding the fact that badly diseased plants were growing amongst the treated plants throughout the entire period. In addition to this, the treated plants were sprayed several times with water containing spores of the fungus parasites.

Scutellista's Latest Victory

By Fred'k Maskew

So much attention and publicity has been given to the achievements of this ubiquitous little friend of the horticulturist that it is with a feeling of diffidence that I offer to you this article. If, however, this apparently acquired taste can be cultivated and developed, it will prove to be the greatest boon the science of applied entomology has offered to the florists of this country.

On Saturday, September 2d, I was called to investigate the condition of an orange tree in a house yard on Cedar street, Long Beach. "The condition" consisted of the most extensive infestation of Lecanium hemisphaericum that I have ever seen upon a citrus tree. To determine the question of proper treatment I removed one of the scales to study the stage of development. To my surprise I found it contained a full grown larvae of some chalcid. This finding was repeated again and again; eventually I found a well recognized pupae, and continuing the search I was finally rewarded by having the adult scutellista emerge from an inverted scale into my hand. In this instance it was not a question of an isolated case of parasitism, but complete and thorough, typical of the work of the scutellista, and characteristic of some of its best efforts uopn Lecanium olea.

Lecanium hemisphaericum can be found in probably every citrus orchard in this country, but it never becomes, or is even considered a pest. It is upon the many different varieties of ferns cultivated under lath and glass that it becomes a serious menace and source of great financial loss. Prior to the introduction of scutellista the writer in an experience covering many years, has never seen an instance of internal parasitism upon this insect. The extreme susceptibility of some ferns to the effects of gas, and the wide range of resistance on the part of the foliage to fumigation, makes even this best of treatments a precarious remedy. To the inspector who has wrestled with the combination of this scale pest, an order of mixed varieties of ferns and a shipping certificate, this latest effort on the part of scutellista is a source of unmixed joy, and by the florist who in the past, despite the use of knife and syringe, has seen his ferns become disfigured with smut, it should be exploited, promptly and persistently.

General Agricultural Notes

VETCH AS A FODDER.

One of the most promising lines of experimental work at the Oregon Experiment Station is that of breeding up the common vetch. We do not think that any other experiment station is breeding the common vetch. This forage plant has already proved itself the foremost in value of annual forage plants for western Oregon. Those who have seen the magnificent crops of common vetch obtained on good land in the Willamette Valley and who know how valuable the forage is, either fresh or cured, may think there is little need of improving it. The common vetch, however, shows unusual adaptation to improvement by the efforts of the plant breeder. Plants have been grown this year at the Oregon Experiment Station which show 25 per cent of protein in the dry matter. The work of the station for the past two or three years shows that the common vetch is richer in protein than even alfalfa, and that strains are being developed which will contain one-half more protein than alfalfa. A strain of vetches which will yield from three to six tons per year of hay containing 25 per cent of protein in its dry matter will be literally worth millions to Oregon. Bran contains only 15 to 16 per cent. Oil meal, the richest in prottin of foods given to stock, contains about 33 per cent. Up to the present time the growing of vetches has been confined mainly to dairy farms, but the vetch will be almost equally valuable to the farmer who is raising cattle for market. It is protein which makes the growth of the animal while the starchy elements in food put on the fat.

THE PARCELS POST.

Is this country so progressive after all? Here is slow old England handling all sorts of packages and produce through its postal system, but obliged to make us turn them over to our express companies when sent to addresses in the United States, because our postal department is too far behind the times to deliver them. Yet when our parcels are mailed to England they are delivered directly to the addresses, as they should be, and without extra charge.

When the American traveller boasts of progress in transportation; our low freight charges, our long distance telephones and rural mail delivery, then the Briton has but to mention "parcels post," and the visitor is silenced. Only the undue power and influence of the express companies can reasonably account for the long delay of an improvement for which the public has been loudly calling year after year. In view of the enormous wealth which the companies have heaped up and divided, it seems high time that the people were given a chance for quick transfer of parcels without paying arbitrary or excessive charges.

While addressing several hundred farmers at the Lowell field meeting last week, ex-Governor N. J. Bachelder, of New Hampshire, said: "While all the classes of people sending packages from one locality to another would be benefited by the establishment of a parcel post in the postoffice department of the government, the dwellers in rural sections would be especially benefited thereby. The parcel post is a logical sequence to rural mail delivery, for by this means the parcels mailed would be taken direct to the houses of the people upon rural delivery routes, which facilities do not exist in express company service. Rural mail carriers could collect and deliver several times the present amount of mail matter without material cost, and through the receipts of a parcel-post system the annual deficiency arising from the rural delivery system might be reduced. The postoffice department that has hitherto turned a cold shoulder toward the parcel post innovation, now recommends a local parcel post over separate rural routes. This is not what the people ought to have, but might act as an opening wedge to something better. The difference to millions of people between sending a package by express for twenty-five cents and by parcels post for six or eight cents, and in the latter case to the door of rural consignees, is an argument that should be given attention by those in authority in the matter."

There is a big difference, too, between paying a fixed and definite charge, regardless of distance or locality, as would be the case with a general parcels post, and paying each of from one to three express companies all sorts of tribute for their share of the work. It is the uncertain and variable nature of express charges quite as much as the actual amount that now exasperates the public.—American Cultivator.

CULTURE OF THE SUGAR BEET.

Many growers of sugar beets have found the crop most exhaustive of the soil and best to rotate it with some other crops. There have also been serious obstacles in the way of manufacture. However, the Sacramento Union sees much in the future of the industry. It says:

The sugar trade is undergoing a transformation that ought to open the eyes of California farmers to a golden opportunity. The suitability of the soil to beet growing is not a matter for doubt. It has been proved conclusively again and again, and the State ought to become one of the great sugar-producing centers of the world.

It seems that a new method has been devised by which the refinery will be thrown entirely out of business. That is to say, the sugar factory will be placed in such a position that it will need no extraneous aid whatever. The raw beets will, as it were, be received at one end of the factory and the finished granulated sugar will be delivered at the other. What is known as "raw sugar" will be handled and refined in the factory itself and the separate sugar refinery will become a thing of the past.

That there is room for an extended beet culture is as certain as California's ability to undertake it. The United States imports nearly three-fourths of all the sugar consumed in the country, and it may be remarked that the consumption doubles itself every eleven years. Every year America pays a sugar bill to foreign countries of $125,000,000 and a very large part of this could be added to the revenue of California. Sugar could certainly be manufactured here at prices that would drive the foreign product out of the home market.

The European sugar industry is now so immense that the mind almost fails to grasp the figures that express it. The capital invested is $650,000,000, and 54,000,000 tons of beets are grown on 4,500,000 acres of land. No less than 1600 factories are needed to handle this trade, of which a substantial part is created by an American demand that ought to be met in America and not elsewhere.

So far as the farmer is concerned the industry seems to be very simple and very remunerative, and the profits will grow still larger with the improved methods. The crop is so reliable where land and water are good that it is usually sold in advance before the seed is planted. So far the beet has developed no animosities in the insect world, and it is patient of drought. Nature seems to have intended the beet for California and California for the beet, and its culture ought certainly to have a future here.

When the Sacramento Valley is self-supporting in the matter of dairy products and helping to supply the whole country with sugar, her prosperity will be even more assured than it is now.

The best engineering—building a bridge of faith over the river of death.

THE INSECT INVASION.

There are now in bearing in this country 165,000,000 apple trees, and not less than $8,250,000 per annum is spent in spraying and otherwise treating them for protection against the codling moth. When this as added to the shrinkage, and full allowance is made for the use of damaged fruit for cider, the bug question must be charged with at least $20,000,000. Other orchard fruits suffer losses equally heavy, and for all of them, including small fruits also, the yearly damage is fully 20 per cent of the entire crop.

Enormous as is the annual loss which may now be fairly charged to predatory bugs, it would certainly be vastly greater if such enemies were left unchecked and no efforts were made to restrict their operations. By the adoption of such means as science has been able to devise for the control of these innumerable foes an immense amount of saving has been accomplished. The damage done by the cotton worm has been cut down from $30,000,000 to $10,000,000; the fight against the Hessian fly saves from $100,000,000 to $200,000,000 annually; defensive measures against the codling moth reduce the loss by $15,000,000 to $20,000,000, and the existence of the orange industry of California has been made possible only by the introduction from Australia of a natural enemy of the white scale—a pestiferous creature which, a few years ago, was rapidly destroying the orange and lemon orchards.—Saturday Evening Post.

College Farm Project.—Renewed discussion appears in the leading papers of this State on the question of the location of the college farm. It will be remembered that the legislature last winter provided for the location and equipment of a college farm. A commission was appointed to investigate the various localities offering sites and to select one which combines the essential elements for a successful agricultural station and farm. So far nothing has come of the scheme, the commissioners have not agreed on any location and the proposition is no nearer solution than it was early in the season.

The Cultivator has discussed this subject quite fully and has taken the position that but one thought should control the commission in selecting a location for the college, viz: to fix it where it can be of the most service to the State; where the best results can be reached for the agricultural classes, with no reference to individual interests nor political affiliations. It would be a most serious mistake to select a location where conditions will not warrant the fullest success to the enterprise, for the college once located can not easily be removed. The members of the commission ought to be well enough advised on the different conditions presented to make no mistake in a final agreement. Soil, climate, water, proximity to market, are all matters commanding careful consideration. It is possible to err in a conclusion on any one of these essentials, but it ought not to be done, for the members of the commission are sufficiently acquainted in the State to avoid making a mistake of any serious character. It seems, however, that Berkeley is moving strenuously to get the college at that place and objections are being urged against the selection on the ground that climatic conditions are not favorable for the best results to the school.

Berkeley is the seat of the State University. It is a great school, the people of California want it to become greater than it is, but whether it is best for the interests of the agricultural college to place it under the influence of the University is a question.

* * *

One of the ablest papers in this State, the Sacramento Union, discusses this proposition, it seems to the Cultivator, very fairly and advances some arguments which should command the consideration of the authorities who have the final say as to where the college shall go. In its issue of August 23d, it says:

"The Viticulturists' Association of St. Helena have spoken out in no uncertain manner. This is a matter that concerns them closely, as indeed it concerns every practical agriculturist in the State. In its broader sense the scheme is for the benefit of the State as a whole. In a narrower and more technical sense it is for the benefit of the farmers. It is a farmers' measure, and therefore the opinion of farmers is of the first importance—of far greater importance indeed than the views of university professors, or even of Eastern experts, who seem to have traveled far for the express purpose of airing those views. The Viticulturists' Association has passed a series of resolutions by a unanimous vote. We believe that the agricultural voice of the whole State will be equally unanimous, and for this reason we append these resolutions, as follows:"

"Whereas, the commission selected to locate the university farm is now ready to select a site; and

Whereas, the bill passed by the Legislature provided that the farm must be for the benefit of the State at large and must be under an established system of irrigation and must represent by soil and climate the great valleys comprising the greater portion of the tillable soil of the State;

Resolved, by the California Viticultural Club of California, composed of viticulturists and vineyardists from all sections of the State, that we respectfully request the commission to conform strictly to the requirements of the bill passed by the Legislature.

Resolved, that we deem the measure to be strictly a farmers' measure and in no wise a university affair, and that the site should be located where it can do the greatest amount of good to the greatest number. We deem it unnecessary that it should be located near the State University, but by all means be located in some locality where the soil and climate are typical of the great valleys of California. Be it further

Resolved, that the Secretary be instructed to immediately forward a copy of these resolutions to each member of the commission."

It would not be easy to find a more terse or a more weighty statement against the selection of Berkeley as a site for the farm. Continuing the discussion, the Union urges, with much terseness the argument which the Cultivator considers both weighty and just, that "the success of the University does not depend upon specialized and ill-justified grants, but rather upon the general prosperity of the State." All of which is true. It should be remembered that the college farm act was in the interest of the farmers in the broadest sense. It was in no way a grant nor a special act to assist any institution nor particular location; it was intended to advance the agricultural needs of California, and any diversion of the purposes of the act will meet with the severest condemnation of the taxpayers of the State.

* * *

The State Fair.—Word comes to the Cultivator that the State Fair, which closes this week at Sacramento, is one of the best held in recent years. Particularly is this true of certain lines of stock interests. Beef cattle have made a splendid showing and this is gratifying, because the interest manifested shows the trend of thought along this line. We have hoped that there would be enlivened interest in beef stock for there is certainly an optunity for its development in the State, especially in the northern part where feed is comparatively cheap. The present exhibition demonstrates that there is an awakened interest in beef breeding cattle; farmers are pushing into Humboldt, Mendocino and other counties bringing with them high grade and pure blood cattle, from which they purpose raising beef of a better quality than the average today existing in California.

Prof. John Craig, of the Texas University, has been appointed to judge beef cattle and other stock, and as he is an authority, we may expect good returns from his judgment.

The dairy interest is alive too, as is evidenced by the fact that some splendid cattle are on exhibition. The dairymen in California are more progressive than the beef men. They have made money right along and they are better organized. For instance, Humboldt county is one of the best dairy organized counties on the Pacific coast. Last year it produced butter that sold for $1,162,793; condensed milk, $62,569; condensed cream, $40,495; total, $1,175,858.

This year Prof. Le Roy Anderson, of San Luis Obispo, is the judge of dairy cattle at the Fair, and we ought to get a good report from him.

We are glad to say more farmers have attended the fair this year than heretofore, manifesting a deeper interest in its welfare. The State Fair ought to be the grand agricultural exhibition for the State and it should be attended by the farmers from every section. It ought to be an educator, as well as a pleasure giver, to those who attend. The Cultivator hopes to see the day when it will rival in attendance the old time State fairs of the Middle West and Eastern States.

* * *

A Valuable Man.—Prof. G. H. Powell, who was sent from Washington, last winter, by Secretary Wilson, to investigate conditions surrounding citrus growing in Southern California, made himself exceedingly valuable to the agriculturalists who were fortunate enough to fall under his instructive talks. He is not like so many auxiliary officials of the various departments in Washington, who assume to know more than the united wisdom of the ages, he simply tells what he knows in a manner so clear and simple that an uneducated farmer finds no difficulty in grasping his suggestions. He is terse but concise, and he leaves the impression clearly that he is honest. The people believe he is competent and he talks not by books alone but by experience.

Well, we are glad to chronicle the fact of the almost certain probability of his coming among us to make his permanent residence. This will be good for citrus growers, as he will be where his advice can be had when questions of doubt, as to what to do, shall arise. Southern California is to be congratulated on the coming of Prof. Powell to abide therein. The citrus growers are likewise to be congratulated that one so capable will be close at hand where advice may often serve them in time of need.

* * *

A Squirrel Law.—While in Kings county recently, a prosperous farmer told us that the damage to his fields and grain from squirrels this year has been very great. Last year it was "frightful," he said, but this year not so extensive, because the heavy rains of last winter killed thousands of the pests. This farmer strenuously advocates a State law requiring boards of supervisors to put poison into the hands of farmers and compel them to clean out their fields. As the rule now obtains about one farmer in ten attempts to poison the squirrels on his land. He gets a few, the rest take fright and hie themselves away to the farms around to add their destructive powers to the army already at work. If a general law were in existence and supervisors were compelled to see to it that it was executed, the gophers and squirels would in a few years become practically extinct, at least, they would do vastly less damage than they are doing at the present time. We are of the opinion that a drastic law should be passed requiring farmers and owners of lots in towns, to make a vigorous campaign against both squirrels and gophers. The expense would be light, but in a short time the results would be ahppily recognized in the decrease of the pests throughout the State.

* * *

Tree Planting.—The season is near at hand when shade and ornamental trees will have to be planted. Make the selection with care, put the right tree in the right place to obviate the necessity of removal a year or so later, then be sure and follow the advice given by Prof. Jepson as to planting. Remember what he says, viz:

"The secret of vigorous growth of ornamental trees lies in proper preparation of the soil before planting. Make the holes at least three feet across and of a like depth—you cannot make them too large or too deep. Do not dump in a lot of manure or trash of any kind, but first put back the surface soil and if possible fill in the hole with nothing but surface soil from surrounding territory, leaving the other soil to be scattered where it may get aerated and enriched. If necessary to use manure let it be well rotted and most thoroughly mixed with the soil before putting it around the tree.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

The prune crop about Watsonville has not been better for years, is of good size, and shows a splendid sugar content.

The Pajaronian says that hundreds of people will be required to handle the enormous apple crop in that vicinity this fall.

The crop of peaches in the Toluca valley is much heavier than was anticipated. The crop will amount to nearly two thousand tons this season.

A car of lemons recently shipped from San Fernando to the East by the Stewart Fruit Co. brought $2490. This is one of the best sales reported this season.

A correspondent writing from Los Gatos says that canneries are preparing to handle the late peaches, of which there is a fair crop and of good quality.

This season has proven one of the worst for years for the seed men in Santa Clara county, the blight having played havoc with almost every variety of seed.

The first pomegranates of the season arrived last week at San Francisco from Fresno. The fruit was of fair size, good color and the sales were made at $1 per box.

Fruit reports from Auburn, Placer county, state that Salway peaches are coming in fast, of which there is a good crop. Cling peaches are also quite heavy and grapes are commencing to move lively.

Six carloads of Tokay grapes were shipped from Florin last week, the two first cars of which sold in New York and Chicago markets at $2180 and $2280 each, which makes an average of $2.25 per crate.

Local florists of San Jose have sent a representative to the City of Mexico with the object of preparing a field for the introduction of California flowers to cater to the European and American trade in that city.

The Patronak winery in Sonoma county commenced crushing some of the earliest varieties of grapes this week. This winery expects to make a large run and handle close to one thousand tons of grapes this year.

The Glenn Transcript says the almond crop in the Orland section is turning out better than expected. P. D. Bane will have about sixteen tons and the Houston orchard will turn off about seven tons. The quality is proving to be excellent.

Some of the orchardists in the Pajaro valley will give their apple trees another spraying before picking time in order to keep the codling moth from getting a start at the last moment. In the valley proper the showing of worms is unusually small.

The almond crop raised on the Bidwell properties was sold to the Chico Fruit Co., on its bid of six and a half cents for hard shell and twelve and a half cents for nonpareil varieties. It is estimated that the sixty tons of various varieties will bring upward of $12,000.

The annual report of the Covina Highland Citrus Union just out shows that it paid the growers for last season's crop an average of $.91 per box, f. g. b. This is exclusive of Valencias, which will bring the average much higher, as some growers received as high as $3 a box.

Fruit shipments from Vacaville are nearly all made. Grape shipments will be much lighter than usual, owing to the heat of July. Up to September 1st there have been shipped seven hundred and fifty cars of all kinds of fruit as against four hundred and seventy-five, same date last year.

The annual report of the Claremont Citrus Union, just out, shows there were three hundred and forty-two cars of Washington navel oranges shipped the past season, for which the association received $140,047. The growers have received $102,965, the average amount per hundred pounds being $1.20.

The grape men in the north central part of the State are on the anxious seat at this time as to the price of wine grapes this season. Some growers are predicting $15 and $18 and even as high as $20 per ton. The wineries about Lodi recently announced their price for wine grapes at $12 but last week raised to $13 on account of counter bidding by Sacramento parties.

The crop of prunes locally is about one-half of a normal yield, runs largely 50-60's, and is worth 3¼ cents. Every packer in the country seems to have sold short and many buyers are here from San Jose, where the crop is not only light, but runs to the smaller sizes. Prunes are apparently sweet, but contain more than the usual amount of juice and lose by evaporation half a pound more than in ordinarily sunny years.—Sonoma County Farmer.

Our correspondent writing from Colusa, says: It may be surprising to many Cultivator readers to know that the best trade in this State, the Palace Hotel of San Francisco, is supplied with oranges from Colusa on the Sacramento river. I today visited the orchard of Col. Jno. D. Harrington, where is as pretty a navel orchard as one would wish to see. Mr. Harrington has had no crop failure and same has not been damaged by frost. His fruit demands the same price as the best Redlands brands and is ready for use the first week in December. he shipping regularly to the Palace and Occidental, and is negotiating this season with the St. Francis hotel. Efforts to start a beet sugar factory here were nearly successful this past season and many are hopeful that they will succeed on another attempt.

AGRICULTURE.

The average crop of wheat in the Fernando valley will be about eight sacks per acre. Barley will average about fifteen sacks per acre this season.

The Sonoma County Farmer says that the crop of hops in that county is estimated at 220,000 bales, the 1600 acres in new hops giving about 2200 bales.

Farmers in the northern portion of Yolo county are circulating a petition which will be presented to the Board oif Supervisors, asking that they pass an ordinance making it compulsory on the part of farmers to put out poison for squirrels.

Boydston Bros. are preparing the ground on one hundred acres of land south of Porterville, to be planted to green peas, cucumbers, tomatoes, egg plant and other vegetables. The land is supposed to be frostless, therefore allowing the growing of very early vegetables.

Frank Blakley is preparing to sow twenty-five hundred acres of wheat in the Lake country in Kings county this fall. To seed this vast tract will take over eight thousand sacks of wheat and Mr. Blakley will have ten six-horse teams at work putting in on an average of two hundred acres per day.

The funds for the Talbert drainage district in Orange county have been secured and bids asked for. The system will comprise twenty-eight miles of ditches, large enough to meet any emergency and when completed there will be no further damage from winter overflows. The system will drain about eight thousand acres and will add considerably to the acreage available for growing celery and sugar beets.

Prof. G. W. Shaw, of the Agricultural Department of the University of California, has been placed in charge of the beet experiment station near Yuba City, in place of Prof. A. B. Stubenrauch. The farm has been moved from the Walton tract to the Gray ranch, just west of Yuba City. Good progress is reported to have been made in the experiments and some two hundred and fifty varieties of wheat from every wheat growing country in the world are on hand.

Grain is almost an entire failure in Glenn county this year and the people are realizing that the only salvation is irrigation. The Central Canal Co., of Willows, is now rapidly progressing on an enormous canal which taps the Sacramento river in Tehama county, and will irrigate 100,000 acres in Glenn and Colusa counties. Plenty of land has been subscribed to guarantee completion and water the year round is sure to mark the awakening of a new era of prosperity for this part of the Sacramento valley. Grain has been the only crop, but after so many years the grain producing vitality has been gradually exhausted until now the old time heavy yields are unknown. By subdivision and irrigation of smaller tracts the crops can be changed, for the fertility and deep soil of this valley is well known, and the homeseeker and investor is all that is wanted.

LIVE STOCK.

At the recent Biltmore Jersey sale 57 head of cows and bulls brought $11,850, an average of $207.89 per head.

Mrs. A. E. Butler, of Forestville, Sonoma county, has a hen twenty years old, which still lays her quota of eggs annually.

G. W. Hunter, of Blocksburg, Humboldt county, has recently bought 2000 sheep from the Saunders band, paying $3.25 per head.

Twenty-two thoroughbred yearling horses from the Spreckels Napa stock farm sold at Sheepshead Bay, New York, last week, for $21,800, or an average of $968.

By connecting the electric plants of Ferndale nad Loleta all of the creameries of the Eel River valley are to be run by electricty.

The Secretary of Agriculture has issued an order revoking in part the quarantine on cattle affected with the scabbies in the States of Eastern Oregon and Washington.

MISCELLANEOUS.

Many forest fires have burned a great deal of timber besides effecting other heavy damages in the Willamette valley, Oregon.

Will Densmore has the best crop of honey in Hemet section this year. From sixty-three stands of bees he has obtained twelve tons of honey.

Wine shipments from the Trenton winery, Sonoma county, are being made at the rate of four cars a day to empty the cellars in time for the new vintage.

Puget Sound mills have been asked to figure on an order for 25,000,000 feet of lumber for delivery in China. This is one of the largest orders ever brought to this coast, and is valued at $2,500,000.

The Maywood Packing Co., shipped its fourth car of dried peaches from Corning last week. The selling price of this last car was eight cents per pound, amounting to $4800 for this car of dried fruit.

A big celebration will be held at Escondido tomorrow, the 9th, at which time the irrigation district bonds will be burned. This district undoubtedly has a great future before it, now that the people have gotten control of their own water.

T. S. Bullock, president of the Sierra railroad, has bought 800,000,000 feet of sugar and white pine timber, situated between the Toulumne and Merced rivers. Some of this timber, comprising three thousand acres, is within the park surrounding the Yosemite valley.

A district fair was held at Ferndale, Humboldt county, this week. The exposition lasted four days and consisted of a good agricultural display and racing. The Eureka fair will be held next week, at which time most of the products shown at Ferndale this week will be shown at Eureka.

The State Board of Trade will give a banquet at the Palace Hotel in San Francisco on the evening of September 14th to Luther Burbank, to fittingly acknowledge the gift of the Carnegie institution of $100,000 in aid of Mr. Burbank's work, and to emphasize the esteem in which the great horticulturist is held.

The special agent of the U. S. Interior Department is at work appraising the lands of the Round Valley Indian reservation, comprising 66,111 acres. The appraising will take several weeks and inside of sixty days the land will be open for filing under the U. S. Homestead laws. The portion which lies in Trinity county can be filed on after October 3d.

The new winery of the Natoma Vineyard Co., near Folsom, just completed, was put in operation last week to crush the grapes in the big vineyard of two thousand acres. The winery was built to replace the one destroyed by fire last September and is one of the largest and finest in the State, costing about $75,000. The Natoma vineyard is one of the two largest in the world.

C. H. SESSIONS, ASSOCIATE EDITOR

EXAMINATION OF DAIRY COWS.

Without going into detail about advantages and disadvantages of different breeds and breeding, some points on how to examine a cow from a profit basis (what she can produce) may be of value to the beginner in the cow business.

First, Will she breed? Does she abort? If so, ascertain when, and the cause of it, if possible. If it is often, you don't want her in your herd, or alone. There are plenty of cows that do not abort, so why fool with her at the price of a healthy one?

Second, Does she give an amount and quality of milk in ratio with her cost? See that the milk is weighed, not measured, and proper test made for fat. Also note the kind of feed the cow is on when examination of milk is made. See that teats and udder are well formed and that she is an easy milker. See that the udder is free from enlargements (lumps) between the lobes, especially the hind quarters. Here are located the lymphatic glands—very easy to detect any enlargement. Also feel for hard lumps in substance of udder. If several are found that have been there for some time, you don't want the cow, as it is very hard to remove this trouble, and in some cases impossible.

Third, after making a thorough examination of the udder and finding nothing wrong, inquire into the history of the cow in regard to age and general health. Often it is hard to find out how old a cow is, especially if over eight. A very good guess can be made by general appearance and the horns and teeth. In young cows up to seven or eight it is not so hard, as they do not get through shedding front teeth until past four years. So you should tell their age as well as in young horses by the number of teeth shed at different years.

The front central incisors come through before or soon after birth. They change at about eighteen months. The next ones at about thirty months and then at 42 months. The last at about four years and three months. With a little practice it is very easy to tell the age of young animals.

Some old cows are very good milkers. As a rule when they are good they were better when younger, but the price can be regulated according to age.

If you are looking for a family cow it is well to learn something in regard to disposition, especially if she is one of the home type. A cow with one eye may be a good animal as far as milk is concerned, but this will depreciate her value, as something may happen to the only eye she has.

So it is well to look to all points. She should be of good size for the breed, well sprung in ribs, large of body and appetite in proportion. Don't look for a smooth, fat cow for a milker; as a rule they are not so good. Drive her across the lot to see is she shows any lameness. Note if she coughs on going in a trot. This is a very good way to detect any disease of the respiratory organs.

I think by going over the cow in a systematic way you will get a better idea of her real value. After a little practice you can make a good examination in thirty minutes, and learn more than if you sat on the fence and talked for three hours about the crops.—Loofbourrow, in Jersey Bulletin.

KEEP CLEAN.

Maybe hog cholera or some other disease has not found you so far this season. The season is not over yet, however, and you may be unfortunate unless you take a bit of precaution and keep your dumping ground clean.

It is surprising how long some people will feed on the spot in dirt and dust without once thinking of what advantage a change would be. Only the other day did a case come under my observation in which a farmer had fed in the same place until the ground was positively filthy. The pigs were not thrifty, and many of them had a cough. It would not be at all surprising if in a short time disease should break out just because of the filth which existed. That is not all—the profits from the entire herd are being lost.

The time to be busy is before such conditions prevail and before disease has made its appearance. In the case mentioned, there is no reason whatever why the feeding troughs could not be fastened on a floor and the entire make up made transferable by team from one spot to another in the pasture, as occasion demands it. This would be far more healthful and decidedly more profitable, and I dare say even more pleasant than the existing conditions.

CONDITION OF BREEDING SOWS.

If the young gilts designed for brood sows are taken away early from those to be fattened and kept growing on grasses and milk, with just enough food in the winter to keep them thrifty, less trouble would be experienced about failure to breed. After they are a year old sows require very little other feed when on good pasture. A few quarts of milk daily has in many instances kept sows nicely when at pasture; or ½ pound of shorts in water, fed daily to 100 lbs. of live hog will do the same.

The chief cause, in most cases, is letting our sympathies get away with our judgment, and we feed the sow all she will eat and just as long as she will eat; so she gets fat, then lazy, exercises but little, and trouble begins. The quicker we stop feeding the brood sow all she will take, and learn to make her grow upon grass with a little grain, and cause her to exercise much, the quicker will failure to breed be known but rarely if at all.

The pig multiplies so fast that under favorable circumstances a shortage cannot be depended upon for a very long time to keep up the price.

Has it ever occurred to you that mule teams are rarely seen on the streets of large cities. The reason is that the hoofs of mules are not able to withstand the grinding of the pavement any length of time.

The health of the hog depends very largely on what is taken into the system through the nose and mouth.

Nothing tends to the thrift of a pig so much as to have him relish his feed at all times.

What You Gain In a few words, you gain this by using a Tubular: (1). One-quarter to one-half more cream, because Tubulars skim by centrifugal force, which is thousands of times stronger than the force of gravity that makes cream rise in pans. (2). One-half to twice as much for butter, because Tubulars remove dirt and bacteria, thus making gilt-edge butter possible. (3). Half the work saved, because you finish skimming five minutes after milking, feed warm skimmed milk at barn, and have only the can of cream to care for. Write today for catalog W-260. It tells all plainly.

An Increase in Profits

Here is the way it figured out for this man:

$52.52 received the month he used the U. S.
25.00 received the month he **didn't.**
27.52 **gained in one month.** At this rate
330.24 is the total for the first year, and
100.00 deducted for his machine, leaves him
$230.24 **net gain,** with his machine **paid for.**

Read the signed statement below:

Delhie, Minn., June 6. 1905.

"I purchased a No. 6 U. S. Separator Feb. 1, 1905, and sold cream the first month to the amount of $52.52, the product of 8 cows. The month previous to getting the Separator the 8 cows produced me about $25. This herd of cows is about the average herd, three of them being heifers. I can heartily recommend the U. S. to all who want a first-class Separator.

UNDULATING LANDS FOR HORSES

English experts are advocates of the theory that undulating lands are decidedly best as grazing grounds for young horses. Apart from the question of the soil, which is in itself, of course, an important matter in the production of nutritious grasses, it is argued that undulating fields are necessary for full and proper muscle development. The perfect horse, or one pleasing in form, needs symmetrical development of all muscles, and the English experts are advocates of the theory that this development is not attained on level pastures; hence their favor for undulating pastures for the best development of all classes of horses.

The simple possession of a good brood sow does not always insure a corresponding certainty of success.

FIGHTING FLIES.

A writer in an exchange says: When I get the cow into the little stable to milk her a cloud of flies come with her, and when I close the door each fly seems to dig his beak into her hide, judging by the way she begins to kick and slash. But the bite is short, for I grab my little sprayer filled with kerosene oil, and with a few pumps of the handle she is relieved of her tormentors. The sprayer blows the kerosene out in a smoke-like mist, which fills the air in the little stable like a fog, and such flies as do not tumble to the floor make all possible haste to get out through the chinks in the building, then I sit down and milk in peace and comfort. The sprayer cost me thirty cents four years ago, and the kerosene I use costs me ten cents a gallon, one gallon lasting about two months. So it will be seen that freedom from annoyance by flies while milking does not come very high. I know of nothing that will clear the flies out of a small stable quicker than a little cheap kerosene delivered through this little tin sprayer. One hot day I saw the cow dashing about among the trees like she had gone wild, and on going out there saw that flies were swarming over her like bees. I opened the gate, and she went to the little stable as fast as she could gallop. I closed the door and turned the sprayer loose, and in less than half a minute there was not a fly left in the building except those squirming on the floor. About ten minutes later I looked in, and there was still a thick fog of kerosene floating in the air, and the cow was lying down chewing her cud.

ACTIVITY NOT ABILITY TO RESIST DISEASE.

The bacon breed of hogs, and especially the Tamworths, have been credited with powers to withstand such infectious diseases as cholera to a much greater extent than the breeds of the lard type or so-called corn-fed hogs. This is largely imaginary, as is also the claim that they possess more stamina That they possess more activity is readily granted, but that they resist such diseases as cholera appreciably better than Berkshires or Poland-Chinas is not supported by satisfactory evidence.

At one time much was heard of the ability of the razorback of the South to resist cholera, but when he was brought in contact with real cholera the myth disappeared, as did the razorback. In short, science and sense, as well as experience and observation, indicate that no breed nor any kind or condition of hog can claim any superior powers in resisting cholera. They nearly all go when a virulent type of the disease is introduced, and all talk to the contrary is the rankest absurdity.—Tait Butler, in N. C. Bulletin.

IS THE JERSEY DELICATE?

In one sense she is. She can not stand neglect and abuse as well as a scrub can. With neglect and abuse you lose money with any kind of cows. What do you keep cows for? To make money. How can you make money if you don't feed and care for them in a humane and intelligent manner? You do that and you will find the Jerseys is not delicate. On the contrary she responds to your treatment with greater profit than any other breed.—Jersey Bulletin.

MALTESE GOATS.

For years the Maltese goat has been regarded in all parts of the world by those interested in raising goats as a very superior animal, not only on account of its milk, but as a breeder. There must be something in the climate of these islands that makes this possible, for pasturage is very scant, and the herds, which are driven out twice a day, seem in some way to find nutriment in places where an ordinary cow would grow poor and pine away. If there is one thing receiving good care at the hands of the Maltese it is the goat, and there are stringent laws in force requiring cleanliness and attention to its welfare. The population of these islands is about 203,000, and almost wholly dependent upon goats' milk. A few cows are kept here, but their milk is not regarded with favor, owing to lack of pasturage. In addition to the limited herbage, the sustenance of the goats is added to by feeding them with carob beans and mixed cotton seed and bran, the extra feed costing about 7 cents per day per goat. It would cost much more to feed cows to produce even fairly good milk, which would render the milk too expensive for general use. For this reason such cows' milk as we have is of very inferior quality and very limited in supply.

It has been estimated that there are about 12,000 goats on the islands. It would be difficult to give their exact number on account of their frequent shipment to Tunis, Italy and other Mediterranean countries. It is an old adage here that no matter how much better a Maltese goat may be fed and pastured elsewhere, it does not thrive as well as at Malta.

There are two varieties of the goat, the short and long haired. In color they are brown or white, about equally divided. As a rule they are dehorned early. The milk produced is of very superior quality, perhaps not as rich as that of an ordinary cow, but, nevertheless, very acceptable for table and cooking purposes. The average height of the goat is two feet six inches, and its weight often reaches nearly 100 pounds. No special attempt seems to be made by the herder in the matter of preserving or refining strains, but, nevertheless, the Maltese goat seems to keep up its reputation for appearance and milk production. As a rule the Maltese goat does not breed before it is fifteen months old; and generally breeds once each year. It is not milked within three months of breeding time and will produce milk until it is eleven or twelve years old.

Very few things are essential to care for the goats. They are kept in herds of from six to thirty animals, and one attendant often has the full charge of and milks the latter number. It is an ordinary sight here to see the herds driven through the principal streets and milked at the doors of residences where milk may be required. This occurs not only once, but two or three times each day, and for this reason householders do not purchase their day's supply at one time, but in small quantities, as it is required. Goats' milk is sold from eight to ten cents a quart. The small quantity of cows' milk sold is bought by a few English residents, and costs about eight cents a quart. Goats' milk is not used here for cheese or butter making. There is a variety of fresh butter and a peculiar kind of cheese produced in the islands, but it is made of sheep's milk. Sheep, however, are very limited in number and need hardly be taken into consideration. The meat of kids, after inspection by the health author-

FARMING LANDS TO LET
For Lease. Two Ranches on Shares. (1) To successful and responsible dairyman, 320 acres, over 100 acres fine alfalfa, 75 high grade cows, registered bulls, 50 brood sows, 3-room house with ample porches; good milk house with steam separator; gross receipts of this ranch last year over $3000. ities, brings about 10 cents per pound. The law requires that they be at least one month old before slaughter, at which time they are to weigh not less than twelve pounds. Goat skins are sold with the hair on, and skins bring from 18 cents upward. The average yield of the Maltese goat is from two to two and a half quarts of milk daily. Its keeping quality is about the same as that of cows' milk, and it is not uncommon for it to keep for twenty-four hours.

The average price for a fair Maltese goat is $15. Some of extra merit bring much more. Most of the persons writing to me desire to know the cost of shipping from here to the United States. This is rather a difficult question to answer, inasmuch as arrangements would have to be made at the American port rather than here. Another thing that should be considered is that it would prove a very expensive, and perhaps useless, matter to ship them singly or in very small numbers. Facilities are very limited on steamers leaving Malta for the United States, I believe, however, that if, say, 100 goats were sent from here to Palermo to be there trans-shipped to the United States, the cost might be estimated at about $1750. This would include the cost of the goats and the freight. Food sufficient to last the herd from Malta to the United States could easily be shipped at this port upon departure. I believe that in estimating the cost of food seven cents per day per goat might safely be reckoned.—United States Consul John H. Grout, Valetta, Malta.

ABORTING COW.

Editor Cultivator: I have a cow which dropped her calf when only seven months along. The cow now has no milk to speak of. The calf is fairly good size but is sustained by other milk. How can we bring her to her milk? We are feeding her twice a day on bran, oat hay and alfalfa. Three weeks ago she quit giving milk very suddenly, and in a few days hardly ate any thing and took very short steps, as if she had been foundered. My milkman thinks it was probably from eating sorghum. The cane was really all ripe and of the first cutting. My neighbors say it is the finest feed they ever raised, and my cows prefer it to any other feed. Is the second and third cutting as good feed for dairy cows as the first cutting? Or is it in reality a good feed for dairy cows?—Subscriber, Highland.

The above was sent to Mr. Burgess, of Arlington, and he answers as follows:

Editor Cultivator: In reply to Subscriber's questions will say: A cow that freshens prematurely (7 months) will come to their milk if milked regularly, but not a full normal flow and will not be satisfactory until after freshening again. Subscriber has, according to his letter, fed her all right, and I think fed her too well (over fed). A cow must properly digest her food to carry out her functions. I infer that not assimilating all the food given her, was the cause of her being stiff and out of sorts. Would give her 1½ lbs. Epsom salts and 2 oz. ground ginger in 2 qts. of water at one dose. Clean out her digestive tract. It is a safe thing to do and might be the means of saving more trouble in the near future.

Sorghum cane is first class feed for milk in connection with prime alfalfa hay. Oat hay is of little value for dairy cows. A little fed once in a while as a change is sometimes desirable. Second and third cut of sorghum is as good as first—if not frosted.—C. S. Burgess.

TO THROW A HORSE.

To thoroughly take the conceit out of a horse there is no better way than to throw him. It certainly requires pluck and determination to throw a horse single-handed, but if done, your horse is virtually conquered for good and all. To do this, says the Horseman, put a good, strong halter on your horse, take a strap with a ring in it and buckle it round the horse's off fore leg below the fetlock joint; take a rope eight feet long and tie it to this strap; place a surcingle around the horse's body; take up your position on the right side of the horse, bring the rope over the horse's back from the off side; take hold of the rope and pull his foot to his body; take a firm hold of this foot, holding it in that position, then take hold of the horse's halter with the left hand, ppull his head to you and press against his body with your elbow, using the words, "Lie down."

The majority of horses can be thrown in this way in under a minute, while others, of course, may fight longer. As soon as the animal has been thrown take the rope that is underneath him, bring it under the surcingle and pass it through the ring of the halter and back under the surcingle again, and thus you have the rope in position to bring his head over his shoulder. Make him put his head on the ground, and if he makes any attempt to get up, pull his head up immediately, which will prevent him from rising. This will give him to understand that you are master. Once a horse realizes your power over him he will do almost anything a horse can do.—Wisconsin Agriculturist.

PROFITABLE DAIRYING.

While down at Compton this week a Cultivator representative visited the dairy ranch of the Sterling Milk Company, a new organization, now owning and operating three ranches, all managed by the well known dairyman, E. E. Moore.

At the home ranch, which is located about two miles north of Compton, we found almost ideal conditions for successful production of milk at a profit. The ranch is located on the new electric road which is being built to Santa Ana, and here is to be located a depot to be known as Lugo (the name of the Moore place). The land lies well, is very fertile, has good buildings, and, above all, has an abundance of good water. One artesian well 467 feet deep has an average flow of 50 inches, while another well is pumped by a gasoline engine. Three silos are used to provide green feed for the stock. One of the silos had just been erected and will soon be filled—it is a round stave affair 13 feet in diameter and 30 feet high. A second silo, about the same size, was filled last week and Mr. Moore was proud of the record made of 15 tons per hour of chopped corn, with his Climax cutter. The third silo is a square one built in the big barn. Mr. Moore says his silage costs him $3 per ton put up. Besides silage for feed, beets and alfalfa are raised and given to the stock.

At this ranch there are two herds of dairy cows, one of about thirty head of registered Jerseys, the other herd of about the same number, are grades, but are great milkers. We were told that this grade herd were each producing about $10 worth of milk per month. On this place there is a skimming station where the milk is cooled and aerated and run through a separator, the cream being sent to the Los Angeles market. Over all, the two things that impressed us most was the air of thrift apparent and the means taken to insure perfect cleanliness in the milk.

This company also owns a ranch at Hynes, where 50 head of registered Jerseys are kept, the conditions being much the same as at the home ranch, and the milk sent to Los Angeles to market.

The third ranch of the company is located within six miles of Corona, near the Fuller ranch. On this ranch, which comprises 350 acres, there have been installed two pumping plants which are producing about 100 inches of water each. A skimming station is being built to handle the milk of 100 head of dairy cows and an adobe barn 60x80 is building. Besides the dairy cows 100 head of Herefords are kept to breed beef cattle. One hundred acres of the ranch have been seeded to alfalfa to furnish feed. Here, as at the two other places, all the dairy product is shipped to Los Angeles to be marketed by the Glen Holly Dairy Company. And, by the way, it will be news to many of our readers to learn that Mr. Moore is no longer manager of this latter company, he having resigned to personally supervise the work of the Sterling Milk Company.

The Glen Holly Company is now in charge of Mr. Fred Smith, recently of Colorado, who has become a heavy stockholder in the corporation. While at the home ranch, Mr. Moore pointed out to us three fine young Jersey bull calves which he had recently sold, two going to Dr. Houston at Imperial, and one to Santa Barbara county. The three sales were made through the company's advertisement in the Cultivator.

In a paper read by A. A. Arnold before a farmers' institute in Wisconsin he made the statement that he had proved by experience that he can make a steer weigh 950 pounds at sixteen months of age, with an average of four pounds of grain feed per day. This makes the cost of grain at one cent per pound, $18. Such a steer sells for about $40 as a "first-class feeder," leaving about $22 for roughage, milk, work, etc. If "finished," the same steer will weigh about 1200 pounds and will have consumed $36 worth of grain, but will sell for about $72, giving a much larger profit than on the "feeder." On this Coast, however, the steer described as a "first-class feeder" would be the best which the market demands, and the finishing of such a steer would not pay. It is probably as true on the farms of Oregon as those of Wisconsin that it pays a great deal better to keep a steer growing as fast as possible until he is about 18 months old than it does to keep him until he is 30 months old. Mr. Arnold further suggests that feeding a scrub is like throwing grain in a sack with a hole in the bottom.—Oregon Agriculturist.

To polish the horns of cattle, scrape with a piece of glass, then rub smooth with sandpaper, using medium rough and very fine paper, and finish by polishing with some good metal polish. The above method is better than using the so-called horn polishes. However, the results depend on the amount of "elbow grease" used. If protectors (flannel lined leather covers) are used on the horns, it requires less work to keep them in shape. Keeping the hoofs clean is about the only attention necessary.

Although farmers are not as particular about their seed grain as they should be for their own profit, they nevertheless show more wisdom in regard thereto than they do in selecting animals to breed from. They will patronize inferior stallions, buy the cheapest bulls, and in various other ways cheat themselves out of handsome profits. There are such things as trusts, and combines, and dishonest officials, but their effect upon the farmer's pocketbook is not comparable to the losses he brings upon himself.

Cows, like some people, sometimes acquire a depraved appetite. If they are forced to drink stagnant water for a time they acqire a taste for it and by and by prefer it to pure water. The lesson is to keep stagnant water out of the pastures.

It is not necessary that a new sow sucking a litter of pigs should lose flesh; after all danger is past feed sufficient to keep her in good flesh.

If too much corn is fed it not only creates too great a heat in the blood of the sow, but makes the milk rich and constipating.

"Do you think our forefathers set up an enduring republic?" "I should say they did. And it's enduring a whole lot more than they ever thought it would have to, I'll bet."—Chicago Record-Herald.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

DRY FEEDING.

(3rd Chapter.)

I wish I could give you the whole of Mr. P. R. Parks' article on dry feeding. I have only room for quotations of parts of his paper. He commences with young chicks on the dry chick feed, which he makes of a mixture of assorted grains. He keeps a dish of beef scraps standing constantly before them, feeds the chick feed in litter with plenty of green food (cabbage or green grass). By this means they have an incentive to scratch from sunrise to sunset, and take their food slowly and naturally. With the beef scrap always within reach, they at no time crave more animal food. Their systems rapidly adapt themselves to the season of plenty and nature constructs a body planned for a continuation of this same diet, namely: good, thick, strong legs and frame, and a chicken that looks ready to eat at any stage of the game, long bodied, short-legged, hardy, "born to live" looking fellows.

When they reach a more mature age, say from six to eight weeks, we place them in colony coops on grass range and soon discontinue the wheat, feeding cracked corn and beef scraps in hoppers, feeding once a week or oftener, as the size of the hopper and number of chicks demand. These hoppers should be made quite high in front, three inches or more, as the birds are always looking for the largest pieces of beef scraps, and with low front hopper waste quite a little by throwing it out with their bills. This system continues until the sexes are separated and then we place the males in yards sufficiently large so that the birds never eat them bare of grass. Placing cull cockerels intended for market by themselves, we compound a mixture of equal weights of corn, wheat, oats and barley, ground fine as flour, if we can induce the miller to reduce it to that fineness, feed it dry and continue the beef scraps. This mixture has given us fatter chickens than we have ever been able to produce by any other system.

A mixed lot of cockerels is about as uncomfortable a set of individuals as is ever gotten together and this is the only system by which each bird can be fed singly. Here each one goes to the hopper and eats as long as he has plenty of saliva, then moves away allowing the weaker brother to come up and take his turn. They must necessarily eat slowly because they can swallow only a small amount of this dry mixture at one time, and thus each one has an equal opportunity.

Here the digestion of the food begins in the mouth. If the crop of one of these birds is cut open, in place of the sour, partly fermented food that is found in a mash-fed chicken, we find the grain as sweet as ever, but smelling as though partly cooked, no fermentation of any kind, and we think the crop now does the work nature intended for it. Your mash fed chicken gets up in the morning, waits around an hour or two until the pleasure of the feeder brings around a pail of hot or cold mash, which is placed on the boards, troughs or other devices, and a wild scramble begins. Each one gulps what he can reach, the weaker get a little, and the stronger the bulk of the feed. If the mash is hot, it raises the temperature of the bird above normal and sweat is started, which is anything but what it should be, laying the foundation of colds and roup. The food goes through the crop with very little change except fermentation, direct to the gizzard and the entire work of the digestive system is thrown upon the gizzard and the intestines; whereas the crop should have done quite a little towards softening and partly digesting it.

With the chickens on range, this hopper of feed awaits them immediately they are off the perch in the morning and they then start upon the day hunt over the fields for the bugs, worms, grasshoppers and grass, which go to make life one sweet dream for poultry. At any time during the day that their appetites dictate they can call at the hopper and get a supply of such food as they desire, and eat it unmolested in a very gentlemanly and ladylike manner. Much more uniform gains result; the younger and weaker chick thrives as well as the larger and stronger; summer chicks grow practically as well as the spring hatched, and bowel trouble is a thing unheard of from the shell to maturity, if the proper heat is maintained in the brooders and the grain and beef scraps used are of the finest quality.

When the pullets go to the laying houses, they are fed cracked corn, wheat, oats and barley; fifty per cent, however, is corn. A hopper of beef scraps is still kept before them, but we now add a hopper of dry bran. The whole grain is fed in litter three times per day. Birds are kept scratching for all their grain but they have cabbages to eat always before them. If cabbages are not plenty we use cut clover, scalded to soften it, fed in deep troughs. We have used with good success a dry mash consisting of twenty-five per cent corn meal, twenty-five per cent beef scraps and fifty per cent bran, fed dry in boxes during the morning, giving what they will eat up by noon when we feed a light feed of whole grain, with another full feeding at night. A good egg yield will result from this ration if the ground grain and beef scraps are of good quality. We would say ninety per cent of the chickens raised in the country do not have sufficient food to develop as they should. Over-feeding would be much better expressed as improper feeding.

As to fertility we think no system of feeding can equal this method. The eggs uniformly test well and the germs live right through and hatch good, strong, bound-to-live chicks that are ready to take up with the dry feed method where their ancestors began. No weaklings result, provided the other conditions surrounding the birds are properly met. Each generation of chicks seems hardier than its ancestors, and are more cheaply raised, for any increase in the general health of a flock must give decrease of mortality.

White Leghorns, Black Minorcas, White Wyandottes and Barred Plymouth Rocks
Trophy Winners at 1903 Los Angeles Show
In each variety my fowls won a share of the regular premiums, and in some thirteen out of a possible twenty-five, or more than all competitors combined. My winning of First, Second, Third, Fourth and Fifth Premiums on White Leghorn Cockerels was the most striking success of the Show. The winning of the National White Wyandotte Club's Blue Ribbon for the best display of White Wyandottes was equally significant. But over and above all, the winning of the Times Eagle Trophy, the most coveted of all the prizes, awarded for the best display throughout, was the most signal and the most important victory of the entire Show. The handsome Cup offered by The Live Stock Tribune was awarded to my stock on the same grounds. These victories only add to an already long list. My fowls have received first premiums wherever exhibited. Over eighty premiums in the last five years.
My fowls are not only standard-bred, but utility-bred. Hundreds of customers attest their merit. They have proven their superiority both in the Show Room and as Breeders. There are no better fowls to be found anywhere, East or West. Both Stock and Eggs sold under absolute guarantees.

When writing advertisers mention Cultivator.

In order to give the method a proper trial make up your mind to try half the flock, for one year with this scheme, starting with the chicks from the eggs, or at any other time that seems best and continuing the experiment until the year is through a full twelve months. The general health of the flock is no small item in reckoning up your assets for the coming season. Be sure and take account of it. So much of the poultryman's prosperity depends upon the health of his flock that any step which may bring up the general tone should be eagerly sought and rigidly adhered to when once found."

* * *

Next week I will try to give a short synopsis of Dr. Sanborn's method of dry feeding and the following week a talk on our enemy, roup.

* * *

EDITOR'S QUESTION BOX.

Rheumatism.—(G. A. J.): I have a half-grown turkey that went lame when it walked. I could not discover anything wrong with its feet. The other foot finally became affected the same way, so that it does not walk at all. It eats, but not greedily. Its feet feel cold to the touch. Can you tell me what is the matter with it, and what treatment will affect a cure?

Auswer.—Your turkey is suffering from rheumatism. For treatment feed an abundance of green food. Give also meat or animal food, and add a little of iodide of potassium to the drinking water. Fifteen grains to the quart of water. Give in small dish to avoid wasting it. This is the best internal remedy. If you are in the country away from a drug store, you can try giving half a teaspoonful of baking soda in a pint of water. Bathe the feet and shanks with the following lotion: One cup of vinegar, one cup of turpentine and as much saltpeter as it will take up (about a tablespoonful). This lotion is excellent for man or beast and suits fowls and turkeys equally well.

* * *

Chickenpox.—(N. Y. C.): I am having a terrible time with my chickens and turkeys. I have never had much sickness in the two years I have handled chickens, but several months ago bought some new White Minorcas, and among them one had very sore feet and legs, and warts on its head, at least they resembled warts. They are hard and black. I have used sulphur and lard, also oil and lard, and succeeded in drying them up, but as fast as I dry them up they break out afresh on some other hen. This morning I feel discouraged and write to you for advice. Some of their eyes are closed and when I open them can pick out sheets of white mattery composition, especially on the turkeys. I feel quite sure it all started from those hens. Can you tell me what it is and what to do for it?

Answer.—Your turkeys and chickens have the chickenpox. It is very infectious, and was brought into your yards by the strangers you bought. It is a germ disease, the germ finding entrance in any slight abrasion, wound or bite and forms a scabby ulcer which may appear on any part of the body, but more often on head, wattles or wings.

It is not often fatal on the old birds, but is dangerous for young fowls. The treatment is to anoint the sores with carbolic salve or carbolated vaseline, washing them off with warm soap suds in which are a few drops of carbolic acid. Disinfect your premises thoroughly and give a little sulphur in the food for a week.

SKIM MILK FOR POULTRY.

A reader of the Farmers' Tribune reports that she can buy skim milk from farmers delivered at her home at fifty cents per barrel, but she is in doubt as to whether it is good business to pay that much for skim milk. Fifty cents per barrel is approximately equal to 16 cents per hundred weight. As a chicken feed, skim milk is fully worth that much. In fact, it is worth that as a hog or calf feed, and it can be fed with greater profit to poultry than to any other farm stock. We, therefore, feel justified in urging our correspondent to give the skim milk proposition a thorough test. Skim milk is especially valuable for young growing chicks, whether they are intended for layers or for the market.

A few years ago the Indiana station made some experiments with feeding skim milk to poultry. The chickens were divided into two lots of ten chickens each, that were from four to six weeks old. The experiment was begun about the middle of July and was continued until close to the middle of September. Both lots were fed a grain ration composed of two parts of crushed corn, one part of wheat bran and one part of ground oats. In addition to this, the chickens in lot one received all the skim milk they could eat, while those in lot two received water in place of milk. Both lots had free access to water, cracked bone, cabbage and lettuce. The lot that received the skim milk gained 4.6 ounces per head per week, while the lot without skim milk gained 2.62 ounces per week. The more rapid gain made by the skim milk chickens was partly due to the fact that they consumed more grain than those that were not fed milk. The average food cost of a pound of gain was 4½ cents, while in lot 2 it was 3½ cents. In figuring the cost of this gain oats were valued at 80 cents per hundred weight, corn meal at 80 cents per hundred weight and shorts at 60 cents, while skim milk was valued at 20 cents per hundred weight.

According to these figures our correspondent can afford to pay as high as 25 cents per hundred weight for skim milk where grains are valued as indicated above and still utilize skim milk to advantage. The wonder is why farmers are willing to sell this valuable product for a price as low as 15 or 16 cents. It is probably true that almost every farmer can feed his own product and derive a greater profit therefrom than he can by disposing of it at the price mentioned.

WHEN BIDDY MOULTS.

(Written for the Cultivator.)

When the feathers fall from the hen
And nearly cover all the pen,
That's the time to keep them clean,
And feed them lots of green.

Don't be discouraged when eggs are few,
Biddy must rest, the same as you. ..
So feed her up with scraps of meat,
And give sunflowers for a treat.

The moult, it is a trying time,
But don't allow your hens to pine;
Give them fresh water thrice a day,
And if you have it, milk or whey.

Keep all their houses clean and nice
And you will have no mites or lice,
And always have a box of grit,
And charcoal, it will keep them fit.

Don't forget to give them shade,
I have always found it paid,
And very soon I think you'll find
That hens will pay, if you are kind.

And if your hens look very ill,
I would not chance to give a pill,
But rather—to change the picture;
Give a dose of "Douglas Mixture."

One of the best foods for laying hens is wheat. Corn should be used sparingly as it is a fattening food and not well calculated for egg production. A certain amount of it, however, may be fed without injury, and no doubt always will be where corn is the cheapest of the grain foods. One can often purchase wheat screenings, or wheat that has been damaged, at a low price per bushel, and whenever this can be done, advantage should be taken thereof by poultry raisers.

Do not waste your time with scrubs. Pure breeds always give the best results, both as to eggs and flesh. Adapt the breed to your climate, soil, and other conditions. Aim to have something superior to your neighbors. Try to get to the top and stay there. Friendly rivalry gives pleasure to poultry keeping. Send some of your birds to your poultry show.

TESTING EGGS.

A simple way for the housewife to test the eggs from a newly found nest, or purchased from the grocery, is to put them in a pan of water. If they are perfectly fresh they will go to the bottom and lie still, directly on their sides; if not quite fresh they will tilt a little and rock about and if very bad, will float on top of the water. It is best to try one at a time.

A little work now, and the expenditure of a few cents for lining paper will serve to make the poultry-house comfortable, with no danger from drafts. Where lining paper is not available, old newspapers, three or four thick, tacked on the walls, will keep out all drafts of air.

Look after the chicken-house window, for a draft is deadly. This question of proper distribution of air is an important one. Let the houses be open every sunny day. Keep them cosy, clean, and comfortable and the reward will surely follow.

Construct your house good and warm so as to avoid damp floors and afford plenty of sunshine; comfort and convenience are more essential than any particular styles; have plenty of ventilation, have the roosts arranged so that they will be away from the nest boxes. Have everything inside easily movable.

The flesh of a duck is of a savory and somewhat of a stimulant nature, and is said to afford a preferable nourishment to that of the goose, being more easily digested, and that of the wild duck is rendered still more easy to digest than the tame, although more savory.

In selling geese it is nearly always best to keep the old ones and sell the young ones, for while the older ones produce the stronger progeny, the younger will bring the best price. In fattening geese for market if in a good condition and well fed, ten days is usually sufficient.

Medicine is good as medicine, but as food it is hurtful and sooner or later bad results will follow. All the stimulants growing and breeding fowls need are wholesome food and drink; these, with clean quarters and opportunities for exercise will keep the fowls healthy.

Hens like to lay in a rather dark nest, the opening of which is hidden from view. If box nests with the opening toward the wall are placed in the poultry house, very few hens will steal their nests in out-of-the-way places.

From this time on during the rest of the summer considerable care must be taken to see that lice and other vermin are not exhausting the growing chicks.

Burnt corn is a most excellent thing to feed to poultry and is far superior to charcoal, which, however, has a wonderful effect in promoting the health of fowls.

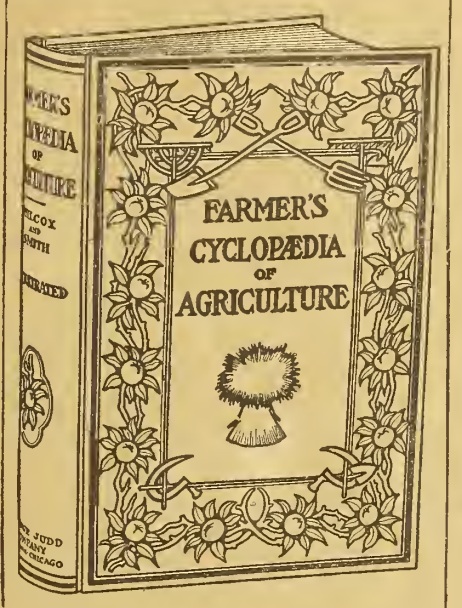
Farmer's Cyclopedia of Agriculture



A Compendium of Agricultural Science and Practice on Farm, Orchard and Garden Crops, the Feeding and Diseases of Farm Animals, Dairy Farming, and Poultry in the United States and Canada

Authors: EARLEY VERNON WILCOX, Ph. D.
CLARENCE BEAMAN SMITH, M. S.
Assistant Editors in the Office of Experiment Stations, United States Dept. of Agriculture

The World Moves

and whoever would not be left behind must lay hold on every means that enables him to move with it. As a basis of one's efforts nothing is more essential than the possession of a good work of reference

Adapted to the Conditions Peculiar to California and Adjoining States

The Farmer's Cyclopedia embodies in its many articles, most of the results of years of painstaking work at the California and neighboring State Agricultural Experiment Stations. It is thus, in effect, both a digest of local and state experience, and a compendium of general knowledge, all of which will prove of indispensable helpfulness to everyone in this section.

The Last Twenty Years of Progress

have measured more changes and recorded more advances in every branch of agricultural science than have been achieved during the hundred years preceding. During all these years no reference book adequately covering the subject has been issued.

The plan of this work is most comprehensive. Every article has received the most careful preparation at the hands of the authors, who have enlisted the co-operation of the highest authorities in the various departments. The greatest educators of the world, representing every branch of agriculture, here unite in one immense faculty to present directly and plainly the pertinent facts of their specialties. Every statement is authoritative and absolutely reliable.

If you wish to know about field crops, garden vegetables, fruits, nuts and other economic plants, farm animals, dairy farming, poultry, also manures, fertilizers, principles of feeding, soils, drainage, irrigation, spraying, veterinary medicines, etc, etc, it is here. Everything concerning farm matters is treated with great thoroughness, though without undue fullness. We claim for it the unique distinction of presenting for the first time, in a carefully arranged and perfectly accessible form, an accurate summary of every subject of interest to farmers, etc.

Over 6000 Topics Indexed
A Wealth of Illustrations

An important part of this work is its very complete and elaborate index, with cross-references under both scientific and common names, so that any information wanted can be found at once. There are between 6000 and 7000 topics covered in these references, making the most perfect index to agriculture ever attempted. It contains 700 royal octavo pages (9½ x 7 inches) and nearly 500 superb half-tone and other original illustrations. Type, paper, printing and binding are all in the highest style of the bookmaker's art, worthy alike of the well-qualified authors, the enterprising publishers, and the industry of agriculture.

PRICE IN HALF MOROCCO, $4.50

To Cultivator readers we make this proposition:—Fill out and sign the enclosed coupon and mail to this office and the book will be delivered postpaid at once and your Cultivator subscription advanced one year.

CUT OUT AND MAIL THIS COUPON AT ONCE

CULTIVATOR PUB. CO., LOS ANGELES, CAL.
Please enter my name for one year (NEW OR RENEWAL) and send me the Farmer's Cyclopedia of Agriculture, half morocco. For both together the price to be $5.00, which I agree to pay as follows: $1.00 on the first day of next month and $1.00 on the first of each of the succeeding four months. Until the $5 is paid in full title to the Cyclopedia to be vested in you.

NAME.....

P. O..... STATE

Our Mountain Forest Trees

By Frank Femmons, Home Orchard, Awahnee, Cal.

Between the Merced river on the north and the Kern on the south, and covering in a continuous belt the mountain sections of Mariposa, Madera, Fresno and Tulare counties, is one of the finest forests of pine, fir and other timber trees in the west, if not in the world. A forest of similar tree growth and species extends from north to south through the entire length of the State, but nowhere else does it reach such grand development of the different species. The redwoods (Sequoia sempervirens) of our northern coast counties and the firs of the Puget Sound country of Washington may challenge the admiration of the world, or the eye of the lumberman, but for diversity of useful species, the size and length of their growth, and their beautiful grandeur as a mountain forest they have no equal and are becoming year by year, more and more the admiration of the thousands from all over the world who visit the Yosemite and other portions of our mountain scenery.

Pine, fir and oak, each of several species, with sequoia (gigantea) and cedar form the larger tree growth, and blooming shrubs at different altitudes or many of them intermingled over a wide range, give a wonderful variety that is pleasing and harmonious, and to one who loves the woods gives a never ending pleasure by their varied forms and groupings. Some of us who have spent a considerable part of life in every day association with their many and ever-changing beauties find their charm the more pleasing as the years go by. There is something in our nature that feels at home in the woods—a feeling as towards some elder brother, binds us to some beautiful monarch of the forest. "The groves were God's first temples," and the towering spires of some forest covered mountain peak brings to the heart the crowning inspiration from the architecture of nature.

When Beauty enrapt at the shrine of the grand,
Is ever advancing through works of His hand,
In mountain cathedral, where majesty dwells,
In sun gilded domes and tree clustered dells.

* * *

But I began this to say something, in my own way, of our different forest trees. It is easy to think of this tree as a pine, or of that as an oak. Certain peculiarities of form, growth, or leaf connect them with some particular class or family. We need not mistake an oak for a pine or a fir for an alder, but most families of trees are divided into many different species, all closely related, as if originally from the same stock. In the United States we have about seventy species of the oak (quercus) family and about forty of the pine. Each species of a family has many characteristics common to the others and some found in no others. When a group of trees resemble each other in their constant characteristics, we think of them as belonging to the same species. Local conditions of soil and climate often cause a difference that is sometimes confusing, and when we observe and remember the fact that every individual tree has its own characteristics—an individuality of its own—no two of them alike, the confusion in names we so often see would seem to be explained, but some of the mistakes are misleading. Quite recently I saw the "poison oak" (Rhus diversiloba) classed among the oaks of California, and often our foothill or gray-leafed pine has been confused with the contorta, the shore scrub pine of our northwest coast, and I have also seen it referred to as the coulter pine, which is found only in the higher ranges near the desert in the southern part of the State. No doubt some dendrologist will pick over the mistakes of this.

Nearly all the forest growth, both tree and shrub, is evergreen. One of the first pleasing surprises every newcomer meets in California is this evergreen character of its tree growth. It is expected in the pines, but to see it in the broad leaves of the manzanita, the laurel and many of our oaks, gives a sensation that is hard to realize at first.

On the line of the Raymond and Yosemite stage road can be seen nearly all the different species found in this part of the State, and in the rich profusion and constantly changing character of their forms and associations, seen as the road climbs higher or winds along the streams or around some mountain side, presents a charm and fascination that gives a new sensation of delight with every turn. During the spring months of April, May and June, our mountain forest is in its greatest beauty.

Soon after leaving the treeless plains of the San Joaquin valley, the oaks attract attention. At first a few scattered here and there among the lower hills but they become more and more numerous as we climb higher. We have seven different species of oak in this part, two of which are evergreen, and one that drops a portion of its leaves in the fall or during the winter, and four are deciduous.

* * *

White Oak.—(Quercus lobata) Is our largest and one of the finest of the family. It is found on low or moist land and will be frequently seen from the low foothills to near four thousand feet altitude. In many places it assumes a noble proportion and aspect—body often four to six feet in diameter, with a heavy wide-spreading crown and arching limbs. Some of them have a pendulus growth—long, slender, vine-like spurs from the larger limbs trailing almost or quite to the ground. The one that gave the name to Big Oak Flat, in Tuolumne county, was over eleven feet in diameter, and still lies there, a fallen monument to the sacrilegious greed for gold. Its prostrate, weather beaten trunk seems yet to express a sorrowing appeal for protection. The few dollars of gold obtained at some time from among its torn up and cut away roots were but a poor return to the world for the life of that tree. As one stands beside it now and lays a loving hand against its still rugged form, with but the decaying stubs of its noble old branches, its mute voice seems to reach the heart—a requiem to the desolation around it.

The dark green, deeply lobed leaves and the darker heavier bark give this species a strong contrast with the

Blue Oak.—(Douglasii.): Growing over about the same habitat, but always on the high, dryer ridges. This tree often assumes some very picturesque forms. One with a rounded, well balanced top is an exception, but once in a while you will see one that seems to have made an especial effort to grow beautiful in shape, and it is certainly a beautiful tree. In many specimens a single limb will grow out in some horizontal direction and would seem determined to have an idea of its own, and get away from the rest of the tree, or perhaps the direction of growth is abruptly turned. I know no trees that will assume so many odd and grotesque forms. The leaves are small, with a general oval shape and their bluish shade of green gives a distinctive characteristic to the tree. It was named for David Douglas, a Scotch botanist who visited California and the Pacific coast in 1826, and first discovered the sugar pine on the upper Columbia river in Oregon, beside many other of our western coast trees. Had he penetrated into the then unknown Sierra Nevadas from his landing at Monterey, what a wonderful storehouse of Nature's choicest tree productions would have met his wandering and lonely steps.

* * *

Black Live Oak.—(O. Wislizeni) Occupies and grows over nearly the same ground as the two preceding, but not so abundant in the lower hills as at a little higher elevation. Usually it assumes a rough, scraggy, scrub growth, but on rich, deep soil attains something of a tree form and it is sometimes fifteen or twenty inches in diameter and a rough open top. The leaves are small, oval in shape and most of them are armed on the edge with stiff, irregular spines, and are glossy dark green, although not so dark as its near relative the Coast live oak (Q. agrifolia) but in habit of growth very similar.

* * *

Chestnut Oak—(Q. densiflora): A few solitary specimens of this species are found here and there in a narrow belt between two and three thousand feet. This is our semi-evergreen oak, but the younger trees usually carry most of their leaves through the year. The leaves are somewhat similar in shape to the chestnut, and the burr produces a very few acorns, some none at all. The trees are so few and scattered that if not pointed out would scarcely attract attention. The finest I know grows by the side of the road in front of the Crooks residence near Gertrude.

* * *

Black Oak.—(Q. Californica): This was generally known until recently as Q. Kelloggi. Why the name needed any change, I do not know, but as it is found in nearly all the wooded sections of our State and at almost all altitudes where trees will grow, and as no one need mistake it in any situation, the new name would seem to be typical. You will find it in the rich little valleys of the upper foothills, along the streams and on the hillsides throughout the timber belt and battling with the storms and the snows on the crags and rocks above, but reaches its best development along the lower edge of the pine belt. It was this tree that produced the acorns that formed one of the principal foods of the Indians.

* * *

Scrub Oak.—(Q. dumosa) (?): I don't feel quite sure of the identity of this. It is confined to a very narrow belt at about 3000 feet. It is a small, growing shrub, but sometimes gets to a height of twenty feet if on good soil and fires do not reach it. The bark is thin and on the larger growth resembles that on the young white oak of the Eastern States. The leaves are deeply lobed and deciduous and the little shrubs produce abundantly the most beautiful acorn of any of our oaks. They drop from their shallow cups as soon as ripe, and as they are quite sweet are soon gathered up by the squirrels and other animals.

* * *

Golden Cup Oak.—(O. chrysolepis): Although this has been reserved to the last in the list of the oaks found in this part of the State, I think it is the most interesting and beautiful tree we have. It is so varied in its form and character that each individual tree has an expression of its own. The body is usually short and frequently divides near the ground into two or more stems, but uniting to form a wide-spreading crown and always, whether growing in an upright or drooping form, seems to be seeking some new ideal of beauty that is found in no other tree. Many of them when not injured by fires or other changing conditions reach almost perfection in many forms of symmetry, and however beautiful we think any of them, we soon learn to expect some new beauty in the next one we meet. One standing in the yard at Home Orchard and each year growing to a nobler perfection, has been imperfectly described as,

The twin-bodied oak, with evergreen crowned,
Whose limbs arching out are reaching the ground—
The dome of its branches a sylvan bower
Where birds chirp and chatter their happiest hour—
The breezes play through it, and shimmer and sheen
Are dancing with light through its dark, glossy green.

This oak is found in almost all situations over a wide range of our mountain slopes above two thousand feet, or about the same as the black oak, but the growing habit of the tree is so much more pleasing and seems in all places to fit into such a perfect harmony with the surroundings, that our forest hills would lose much of their charm without it.

The best medicine—cheerfulness and temperance.

Queries and Suggestions

THOMPSON'S SEEDLESS CUTTINGS.

A subscriber at Edenvale wishes to know where he can secure cuttings of the Thompson Seedless grape.

Almost any grape grower can supply the cuttings desired, or we are sure either the Fancher Creek or the Fresno nurseries can do so. Either can be addressed at Fresno.

ESTIMATING LUMBER IN LOG.

Editor Cultivator: How many feet of lumber in a log two feet in diameter and one hundred feet long? Uniform in size from butt to top. The log is not supposed to be sawed into lumber, but just estimated. This is to settle a wager.—A. B. G., Ukiah.

The Cultivator not being a lumberman's paper, has no specialist on hand who can figure out for our subscriber the number of feet but, by reference to tables, we can give him, perhaps, fairly accurate figures. We take it he means regular board measure, which assumes the lumber to be an inch thick. We find by reference to tables that there are some forty-three systems of scaling logs. The oldest of these is called Scribner's scale, which is approximately an average of the others, for we note there is much diversity in them as to the amount of lumber which is contained in the various sized logs. However, taking the Scribner system as a basis the log which you mention would contain 2525 feet of merchantable lumber.

CARE OF VINES.

Editor Cultivator: Do Loganberries need water at this season? Shall I let tops die or cut off? Also shall I continue to give blackberries and raspberries water? Also, have a bed of Jessie strawberries, set one year ago. Bore a fine crop this season. Will they bear next season, or will I have to set new plants? Do strawberries have to be irrigated through the dry season? Which is better, to let the vines run or keep them in hills? Should asparagus be irrigated after crop is gathered?—Subscriber, Fallbrook.

The loganberries, blackberries and raspberries should be kept in fairly good growing condition during this season for the formation of strong canes for next year. Care should be exercised also in removing the canes of last year's growth which bore fruit this year. In fact, this should have been done immediately after removal of the fruit. Blackberries and raspberries should have the new canes topped, so as to induce branching out and giving more bearing wood for next year. Strawberries should have sufficient water to keep them alive, for they will not live through the summer season unless some water is given. Withholding water is often done to induce bearing at a certain period later, but this is not carried to the extent of allowing the plants to die, of course. The keeping of the vines in hills has the preference, for if you allow the suckers to root and make a complete mat of vines all over the row you will not have as large and desirable fruit as where you hold to one vine to the hill.

The asparagus should be kept in the best of growing condition during the earlier part of summer and later may be allowed to become partially dormant. Care must be taken not to allow it to dry out entirely, however, and then put on the water in midsummer, because this induces an out-of-season growth which is not best for the plants.

NON-BEARING PEACH TREES.

Editor Cultivator: I have large, thrifty peach trees that continue to run to wood and foliage, almost no fruit. Fruit is similar to the Crawford, but I wish to know what to do with the trees, or should I grub them out?—Mrs. C. E. McL., Ioamosa

It will be hard to give explicit directions as to what to do in such a case on such information, but if you find the fruit exceptionally fine, as we note you say it is similar to the Crawfords, it might be well to try summer pruning. Very severe summer cutting has sometimes made some trees bear very heavily. It should be done immediately after removal of fruit of the last year. This heavy cutting, topping back the entire summer's growth, or even more, tends to shock the tree to the end that it sends its vitality into fruit buds for the next year's fruit instead of continuing to send so much of its sap into wood growth. "Summer pruning for fruit; winter pruning for wood," is on old adage of the pruner.

UNFERMENTED GRAPE JUICE.

Editor Cultivator: Will you kindly ask for recipes for manufacture of unfermented grape juice?—H. C. M., Gaviota, Cal.

The Cultivator has in the past had extended articles on this subject and now refers the subscriber and others to Farmers' Bulletin No. 175, "Home Manufacture and Use of Unfermented Grape Juice," which may be secured by writing the Department of Agriculture, Washington, D. C.

ALKALI LAND.

Editor Cultivator: Kindly give information about black and white alkali land and advise me if such land is of any value. Does irrigation cause alkali to come up?—S. E. S., Livingston.

Black alkali is of such a caustic nature that but few seeds will exist in it, where in any quantity. Some white alkali land has proved remarkably productive, for it is almost invariably the case that all alkali land is rich in plant food. The black alkali may be changed to white alkali by the use of a liberal coating of gypsum or land plaster. But the best way to remove either from the soil is by a system of tile drainage which, while expensive, makes some of the most worthless of land, the most valuable. That is work which would require experienced men to direct, os that instruction in this paper as to detail would hardly be of service. Irrigation does not cause alkali, but does cause the alkali to come to the surface and become more apparent through the solvent nature of the water coming to the surface through irrigating, leaving a greater deposit on the surface than was perhaps originally observable. But where the land is under drainage the irrigation all helps to carry the alkali out of the soil.

Some plants that are excellent for forage, like the Australian salt bushes, have done well on land which was quite strongly impregnated with white alkali but most cultivated plants will endure but a very small percentage of it in the soil.

GOOSEBERRIES.

Editor Cultivator: Do gooseberries do well in Southern California? What are the varieties best adapted? Is there a law prohibiting the building of a fence on the line? Do rabbits or Belgian hares have roup, same as chickens?—Subscriber, Glendora.

Gooseberries will not do well in the drier and warmer parts of the State. In fact they have never done well south of Tehachapi and are of very limited culture. The Downing is probably the favorite, if any variety is to be planted in that end of the State.

Certainly there could be no preventing the building of a fence along the line. As to whether you can build on the line, compelling the neighbor to join in the building of the line fence, we question. In fact, one attorney has informed us that it can not be done.

The query as to Belgian hares we are unable to answer, for while there are some diseases which affect them, we cannot say whether they would be affected by the poultry diseases or not, and ask our subscribers who have had experience along that line to inform us.

BELGIAN HARES.

W. Robinson, San Bernardino, can perhaps get the stock he wants by writing to Edward Ochs, Moneta, Cal.

BUFF ORPINGTONS.

Mrs. V. V. Jerome, of Downey, Cal., writes us in answer to query that she will be able to supply newly hatched Orpingtons in about ten days. Mrs. Jerome ought to place an ad in the Cultivator.

EUCALYPTS FOR THE FARM.

(Continued from First Page.)

foliage has yielded by distillation 64 oz. of lemon scented oil.

* * *

Other Uses.—No mention has been made of the importance of eucalypts as honey plants, yet nearly all species are valuable for their honey yield. One species (E. terminalis) known as the manna gum, yields a sweet gum much relished by the natives as an article of food. Several species yield heavily of tannic acid, yielding above 65 per cent. One quite extensively planted in California (E. tereticornis) yields 62 per cent of tannic acid and 28 ounces of oil from 100 pounds of dry leaves. E. naemastoma, which yields 66 per cent of tannin, gives 33½ ounces of oil from 100 pounds of green leaves. E. sideroplhoia, well known here, yields 28 per cent of tannin and 42 per cent of arabin, by which it will be seen that they yield numerous products of commercial value. In Australia the leaves and small branches of E. microtheca are placed in water to poison fish and the inner bark of the same species is used as a poultice for snake bites.

THE ROSE AND THE LILY.

In the long, long ago, so they tell me,
In a garden (where, nobody knows),
There grew a sweet, modest white lily
And a homely, old-fashioned rose.

And they both loved the amorous West Wind,
Just why, I'm sure nobody knows,
And the Wind was in love with the lily
That grew by the homely white rose.

In the night came the amorous West Wind,
Confused by the dark, I suppose;
And the kiss that was meant for the lily
Was pressed on the lips of the rose.

And ever since then, so they tell me,
Wherever a sweet garden grows,
There's a paleness of grief o'er the lily,
And a blush on the face of the rose.

San Francisco Bulletin.

SATURDAY NIGHT.

Placing the little hats all in a row
Ready for church on the morrow, you know;
Washing wee faces and little black fists,
Getting them ready and fit to be kissed;
Putting them into clean garments and white;
That is what mothers are doing tonight.

Spying out holes in the little worn hose,
Laying by shoes that are worn through the toes,
Looking o'er garments so faded and thin—
Who but a mother knows where to begin!
Changing a button to make it look right—
That is what mothers are doing tonight.

Calling the little ones all round her chair,
Hearing them lisp forth their soft evening prayer,
Telling them stories of Jesus of old,
Who loves to gather the lambs to his fold;
Watching, they listen with childish delight—
That is what mothers are doing tonight.

Creeping so softly to take a last peep,
After the little ones all are asleep;
Anxious to know if the children are warm,
Tucking the blanket round each little form;
Kissing each little face rosy and bright—
That is what mothers are doing tonight.

Kneeling down gently beside a white bed,
Lowly and meekly she bows down her head,
Praying as only a mother can pray,
"God guide and keep them from going astray."

The Strike at Nixon's

PART II.

Mr. Nixon's temper and temperature rose simultaneously. Here was a hen—or possibly a rooster which might have been sold in the fall, to be eaten at a picnic. Besides, there were all those other expensive things. They had dared to prepare them and go without his consent! In fact, was not this open defiance of him? Yes. They would find out now "who was who!" Then, too, he had found Aunt Clarida Perkins and her reticule, whom the stage had conveyed hither, waiting patiently on the doorstep till someone should appear. Reluctantly he drove with her to "Cousin Abiram's," three miles farther on. Another hindrance because the women were not at home!

As might be expected, the interview upon their return was a stormy one. He rightly guessed that Viny was largely responsible for the act, and spoke accordingly. Mrs. Nixon had been acquiescent so many years it would hardly be wise to credit her with revolt. But, in thinking to subdue Viny, he "reckoned without his host." True, she was only a woman—but she was a Nixon!

"You can take your choice," he declared in conclusion. "Remember now, no more of this galavanting round the country or you can pack your duds an' get right out, for good an' all, both of you!" this last spoken in the italics of suppressed rage as he left them.

Mrs. Nixon was frightened. Viny stubbornly defiant. They held a long consultation in the parlor bedroom.

Mr. Nixon's note for the next day read thus: "Pa: We are taking the stage to Freeport, duds and all. We have enjoyed a little rest and change and being like other folks. We shall stay to Uncle Rastus's till Sunday and just let on we are visiting. If you want us to come back bad enough to give us the egg and butter money and a chance to go, once in a while, without being grumbled at, come for us then and we will work for you same as always. If not, we shall tell why—then go into the factory and take care of ourselves. Viny."

He was nonplussed, angry, chagrined. It was a thoroughly unexpected move; yet he believed himself master of the situation. His eyes which once were a fascinating, changeful blue, now turned to a stern, loveless gray, with a foxlike cunning lurking about them.

Sunday afternoon Zed drove to Freeport, a willing but unconscious participant in the comedy tragedy being enacted. Immediately after, Mr. Nixon caught up his hat and crossed the road. Restraint was gone. A beastly ferocity came to the surface.

"I'll learn the little Luzzy a lesson she won't forget! She don't defy me again! I reckon this'll cut into her high-flyin' notions," and he fingered the rawhide lash of a whip. "It's that damnable 'woman's column' that's to the bottom of it all—I know 'tis. When she's spent a few days in the corn house chamber on prison dainties, she'll let 'well enough alone,' maybe!"

The corn house was really a small granary. Below were grain bins and a tool room; above, corn, ground feed, and broken castaways without number. Searching among miscellaneous irons in a nail keg, he finally drew forth a short chain, two staples and a padlock; with these and a hammer he went upstairs. Heavy blows racked the thin partition which divided the corn room from the rest, as the staples were driven deeper and deeper. The chain rattled against the door latch and broke in upon the Sabbath stillness, with a wierd, uncanny sound; but the man, listening, laughed exultantly.

Inside, a window in the gable was half hidden by spider webs, black and dust-laden. He laughed again. "Guess I'll leave 'em; she hates 'em so it'll make it worse an' worse." A broken chair and a heap of grain bags were thrown into a corner. "She can make a bed of them, or set up, just as she likes!" he muttered. Then he locked the outer door as he left, taking the key.

At Freeport, Viny and her mother were getting anxious.

"It's 3 o'clock an' he hain't come yet! Whatever'll we do if he don't?" whispered Mrs. Nixon as she drew Viny to one side. Her voice trembled. "Why just what we said we would, of course." Viny was not as sanguine as her voice implied, but hers was the Nixon spirit—not easily quenched. "If there isn't Zed coming!" she exclaimed rapturously a few moments after, and she rushed to the door. Her father had relented! The fact turned her head and she appeared unreasonably glad to see the hired man. Aunt Mary looked at her quizzically, wondering if "the girl were in love with that gawky."

"Gosh, yes, Mis Nixon! Jim's all right; he just 'lowed he'd ruther do chores than be jounced over these rough roads," Zed explained in answer to the wife's anxious inquires. "'Good 'nough, good 'nough, says I to him; for me, ridin' 'tween two such nice women's just like bein' the meat in a sandwich,' an' I slid into me meetin' clothes 'fore he had a chance to change his mind!"

The atmosphere was insufferable: not a leaf stirred. Waves of heat came up from the scorched earth, and the spokes in the wheels of the old democrat, rattled noisily over the stony highway. The horse stopped often to rest, panting for breath. Humanity seemed suffocating.

"There won't be half a pint left of me, time we get home!" Zed remarked as drops of perspiration rained off his forehead over his big face.

At this moment a breeze sprung up, cooling, welcome. Zed turned about surprised.

"Spooks o' Caesar! look behind ye. We'll need the ark next!" and he urged the tired beast into a trot.

Along the western horizon lay a dense mass of clouds, creeping up like some giant from an ambush. White, feathery portions were flying across the sky as from an enemy. The sun was soon hidden and a yellowish murky light took its place. The air grew strangely chill. Trees were now bending low in the gale and the first drops of rain fell as they alighted at the gate.

"Git them windows shut quicker'n scat!" commanded Zed; then, grasping the horse by the bits he started on a run for the barn, where, the moment he was released, the animal dashed under cover. Here, Zed felt himself lifted, carried—whither? He was dimly conscious that the wagon was being hurled end over end toward him. Fences fell like straws. There was a crash, then—forgetfulness!

Blackness of midnight seemed settling down. Yet the lightning gave flash views of the devastation being wrought.

Down cellar, crouching in the darkness, Mrs. Nixon and Viny listened in breathless suspense. Immense hailstones struck and bounded along the kitchen floor; the window panes must be broken! Viny felt rather than saw that her mother was kneeling at a preserve jar beside the vinegar barrel. Where was her father? Should she ever see him again? Why did she dread meeting him? Her thoughts added terror to the situation.

When the storm ceased, she spoke; there was no reply. She touched her mother; but there was no motion. She had fainted,

Terrified, Viny flew upstairs and out into the rain which was falling drowsily now. Could it be? She looked again. Yes, the horse barn was minus its roof and the corn house lay in a heap, crushed by the giant who came out of the west.

She called, frantically. Something like a faint echo answered her once—twice. Running to the farther barn, she called again. The answer was nearer. Back, on a rise of ground she found her father, pinned face downward under a fallen tree limb.

"Oh, pa! are you killed?" she asked,

HELP!

dropping down so as to peer under the branches.

"Not quite. Lift this off'n me! You can't? Get the saw—it's in the corn house—and break up the top."

She was gone. Then he remembered the corn house was locked! Had he, in his unrighteous anger toward her, sealed his own fate? He shrank from death. He must live. Yet how could he? This weight was crushing him! His life, with its mistaken ideal, the wrongs heaped upon the wife and child, rose before him. He tried to pray, and seemed to hear demons laughing at his misery!

Viny came, at last, bringing only a long pole and a saw horse. Then he heard the clink of a chain. Would she ever know about that other one?

"O, why don't somebody save my life! I can't breathe much longer," he moaned.

"You keep breathing," she commanded almost sternly in her anxiety. "I'll have you out in a minute!"

Crossing them at right angles, she bound the limb and pole together, placer the 'horse' underneath the latter, and then threw her body across its upper end. Her purpose was accomplished. The lever worked and the branches lifted a trifle. She crept farther out on the pole. The limb raised higher.

"Crawl out quick, pa! I can't hang here long." Her feet were off the ground and her temple veins stood out, rigid with the struggle.

He tried to obey her. Just then Mrs. Nixon staggered round the barn and in another instant was assisting the almost unconscious man to escape from his perilous position. Another moment and Jim Nixon's head was pillowed in his wife's lap.

"O, Ursula, it's too late to do different, but I hain't lived right—I see it! That woman's column was gospel! I'd orter divided, but I coveted the gold you helped me earn, an' kep' it like a brute! I wisht I'd give you more. Get the hen park and the pans and the muslin—when I'm gone—get back the comfort I stole from you! Yes—I was plotting against the child God gave me—against her mother, too, but He said: 'Thus far shalt thou go and no farther!' I heard it in the thunder! He struck me down! And to think I turned you out and then you—saved me! Forgive me—goodbye!"

Here, Zed came from somewhere, dazed and limping, but at sight of his employer, forgot that he was bruised: together they carried the half dead man to the house.

The delirium which followed, revealed the terrible secret of the corn house chamber, and Viny shuddered. He reviled them, drove them from him with curses. Later, he begged them to come back—prayed that they would not leave him to die alone! The mind mirrored the soul's passionate struggle—love against greed.

"Viny," he whispered one morning when reason had returned, "if you don't hate me, kiss me, child; tell me that you forgive the old pa that died in the tornado, and 'll help the new one to live better."

'I didn't do right, either, pa. I drove ma into acting so, just for spite," and Viny's tears glistened on the man's gray locks.

Her kiss, repentance and confession—how they comforted him. And he had thought to gain the latter with the lash!

"Never mind, Viny; you're worth more'n board'n clothes to me, now. We'll start new—work for each other's interest this time, 'n call the firm Nixon and Company.' Read me a little scripture from St. John and the 'woman's column' "!

Cookery Recipes

CANNING FRUIT.

Editor Cultivator: As I have been a constant reader of your prized paper, I will add my mite to the household department.

I notice all the recipes for canning in glass jars advise that after they get cool turn down the cover a second time. Now that is just what causes much good, costly fruit to spoil. The first seal is the only true seal. I have put up over 200 qts. of different kinds of fruits and not one has made a bubble yet.

This is my way: I fill all the jars I can get in a tub without being so close together as to crack any. Put on rubbers and tops and screw tight, and then unscrew one turn so all air can escape while they boil, then put on cold water two thirds the way up the jars and set on a hot fire. Cook rapidly till all are done. Now have on the stove a saucepan full of the same kind of fruit with a good thick syrup, and draw the tub off of the fire and let set two minutes to let the bubbles break out; let the fruit settle. Fill to overflowing and screw each top down as the jar is filled and hold upside down, and if it does not drip any juice give the cover one more turn and stand it on its head and leave till it can be handled bare handed, then turn heads up and never break that first good hot seal. If fruit is very sour put the desired amount of sugar in on top of the fruit before cooking and it will settle down as it cools.

Now, all who try my way I am sure will never fail. I have fine luck with the jar called the Lightning, also the Everlasting and I like the Standard Mason. All are good. I hope this may be of interest to a great many housekeepers.—Mrs. M. E. Seeley, Arroyo Grande.

* * *

BENGAL CHUTNEY.

Editor Household Department: In response to your recent request for pickle recipes, hand you herewith one for Bengal Chutney sauce.—Mrs. Frank Morse, Santa Ana.

Bengal Chutney.—9 ripe tomatoes, 13 large apples, ½ lb. onions (chopped fine), ½ lb. stoned raisins (chopped fine), 1 lb. brown sugar, 3 oz. salt (or to taste), 2 oz. ginger, 1 oz. cayenne pepper, 3 pints vinegar, 2 oz. ground mustard, 1 oz. tumeric.

Stew apples and tomatoes and put through collander. Add all other ingredients except mustard. Let boil a half hour. Add mustard dissolved in a little vinegar. Cool and bottle.

* * *

Carrot Pudding.—Americans do not fully appreciate this vegetable. They feed them to horses to give glossy coat, and do not realize that their own complexions can be benefited by the use of the same vegetable. Here is a delicious pudding: Boil and mash enough young carrots to make a half pound of pulp; add to this a large cupful of grated crumbs, four ounces of flour, four of butter, eight of sugar, and the same of dried fruits, currants, raisins and citron. Pour into a buttered mold, and steam two and a half hours. Serve with sauce.

Young Carrots in Lemon Sauce.—Wash small young carrots and cook in salted boiling water and cut in halves lengthwise. Scrape off the thin skin and put in a saucepan with a saltspoon of salt, a rounding tablespoon of butter, a dust of pepper and a rounding tablespoon of sugar. Set the pan on the back part of the range, or in another pan partly filled with boiling water and simmer until the butter is absorbed; then pour over a tablespoon of lemon juice, stir it in lightly and last sprinkle with a teaspoon of finely chopped parsley and serve at once.

* * *

Lentil Croquettes.—Boil half a pint of split lentils that have been soaked over night until tender and run through a puree seive. Cook a sliced onion in butter until yellow, add a chopped tomato and salt and pepper to season. Mix these ingredients with the lentils, and let the mixture get cold. When quite firm shape the croquettes, dip in egg and bread crumbs and fry a rich golden color. These are nourishing and sustaining, yet very cheap.

* * *

Tomato.—One can of tomatoes pressed through a colander, seasoned with salt and pepper and cooked well for ten minutes. In another saucepan heat to boiling point one quart of fresh milk, to which add either one large square cracker rolled fine or one even tablespoonful of flour rubbed into one tablespoonful of butter. When the milk is slightly thickened add it to the tomatoes and serve at once. It is likely to curdle if it stands too long, or if the milk is not perfectly sweet.

* * *

Corn.—One can of corn rubbed through the colander and one quart of hot milk added, with a piece of butter, pepper and salt, makes also a very nice quick soup.

HOMELY HINTS.

A Chicago woman who manages a famous restaurant in that city originated an asparagus patty which is greatly relished by her patrons. The patty is the usual case of puff paste, only it is made long instead of round, and just the shape and size to hold short stalks of asparagus. A delicious Hollandaise sauce is poured over the patty before serving.

Cheese may be kept from being moldy by wrapping it in a cloth dipped in vinegar and wrung nearly dry. Cover the cloth with a wrapper of paper and keep in a cool place.

It is not generally known that eggs covered with boiling water and allowed to stand five minutes are more nourishing and more easily digested than eggs placed in boiling water and allowed to boil furiously for three and a half minutes.

A few drops of turpentine sprinkled where cockroaches congregate will exterminate them at once, it will also drive red and black ants away.

Iron white clothes on the right side, but calicoes, ginghams, etc., on the wrong side, to produce the lusterless effect seen in the new material before it has been laundered.

When washing dishes which have held milk, rinse them with cold water before placing them in hot water.

Broiled fish, like beefsteak, should not be salted until nearly done; the salt hardens the fiber and draws out the juices.

Doors that will not open easily and drawers that stick may be put in good condition by rubbing the offending edges with stove blacking or even a soft lead pencil.

Brass, if much discolored can be cleaned with oxalic acid. Polishing of brasses may be avoided, if, when they are in fine condition they are varnished with a colorless shellac kept in any paint store.

A simple polish for furniture can be made of one part turpentine and three parts linseed oil. Apply with plenty of "elbow grease." If the children see you use it, they will want to "do it too." Let them try on their own little rockers. It will have a double effect—beside the polish a desire to take care of things.

When a broom has been used for heavy sweeping it keeps longer if it is dipped in hot water, shaken out well and allowed to hang up till dry.

A pair if old kind gloves, large size, are good to put on when you sweep or whip rugs or trim vines.

ENCOURAGING.

"But, Mr. Rounder, I never gave you the slighest encouragement!"

"You didn't, eh?"

"I certainly did not."

"Didn't you tell me you wouldn't marry the best man on earth?"—Houston Post.

VETERINARY DEPARTMENT

BY DR. W. J. OLIVER,
318 East Second St., Los Angeles.

To the end that this department may be made as valuable to the subscribers as possible, we ask observance of the following: Be sure to state in full the history of the case, location of the disease and the conditions under which the animal has been kept just before and since the disease ap eared. Give your name and address, which will not appear in the paper if you so request. No charge whatever is made for such questions as are answered through the colums of the Cultivator, but when an immediate mail answer is wished Dr. Oliver asks an additional fee of $1.00 and will give immediate attention and reply by mail. In such case write Dr. W J. Oliver, 318 E. Second St., Los Angeles, Cal.

Questions should be in by Monday to be answered in the following Friday's paper.

CHRONIC INDIGESTION.

Editor Cultivator: Beg to state the valuable mare I asked advice about some three weeks ago has died. I had veterinary working with her for some time and he was giving similar medicines to those advised by the Cultivator veterinary. Now, we dissected her; some organs slightly affected with the long illness, but the trouble was chronic trouble of the large intestines. They were some bloody and looked to me like action of glass, and the mare literally starved herself to death. Can you tell me probable cause of this? I only owned her seven weeks. Do you think it might be glass in the barley?—J. G. Harmon, Santa Ana.

If glass had killed her you would have found some of it in the stomach. I think it was chronic indigestion.

DRY TEAT.

Editor Cultivator: I have a good six year old Jersey cow that I got with the ranch when I bought it. She was giving milk when I got her out of three teats, and the other has been dry. She will be fresh in about two weeks, and her udder enlarging some, and I milk a little on ground once each day, as she don't seem to go clean dry. I notice the fourth teat (the left front one) will let a few drops of milk through still. I want to know if there is danger of milk being in that quarter of her udder that has the dry teat so that I cannot get the milk out, and cause her udder to spoil? If milk cakes in it and I cannot get it out, what shall I do with it? Is there any way to bring the spoiled teat to its proper functions? If so how? Please advise in first Cultivator and greatly oblige.—J. G. Harmon, Santa Ana.

The teat will very probably remain dry and cause no further trouble. If milk should come in that quarter you may draw it off with milk tube. If it don't become inflamed let it strictly alone.

SITFAST.

Editor Cultivator: I have a mare six years old in good condition. Seems to feel all right, but she has something on her neck. There seems to be a black scab formed on top of her neck; it is thick and heavy. Puss forms of a very bad odor. I have been using carbolic acid on it and it has eaten down almost an inch, and seems to be spreading up her neck. What ails her and what is the remedy?—J. H. R., Imperial.

This is called a sitfast. It will be necessary to dissect out the dried chore or scab, then cleanse the parts and apply the following lotion: Sulp. zinc, 2 oz., sugar lead, 2 oz., water, one quart. Shake and apply three times a day. Dust on compound alum powder after using liquid.

SORE EYES.

Editor Cultivator: We have several cattle that are so blind with what we suppose is the pinkeye that they fall off a bluff or into a ditch and are liable to be killed at any time. How shall we doctor them?—P. T. Buell, Ballard.

You don't describe the symptoms so I can define the disease. Use the following, inserting about the size of pea in eye once or twice a day. Blue ointment, one-half dram, lanoline, two drams, vaseline, two drams. Mix.

RYE—Good to choice, per ctl., nominal; new, $1.47½@1.50.

CITRUS MARKETS

In the citrus market very little is to be said. But few cars are going out of California. The fruit that is arriving at the auction points in the East in good shape is bringing good prices, although not quite as large as last week. The market at New York has been partially spoilt for oranges on account of the fruit being in bad shape.

Lemons still command fabulous prices, owing to the great scarcity. Practically none of this fruit is being received from Europe and only from ten to fifteen cars a day are going out of California. This supply for the United States comes nowhere near meeting the demand and everything is being taken as fast as offered.

A dispatch in the Los Angeles Times of last Sunday, from New York, in reviewing the lemon situation, says that "not for ten years has the supply been so light as at this season of the year. There are noly about ten thousand boxes in sight. Those will not last very long when the demand is as strong as it is now. One buyer would probably be able to place every lemon of the ten thousand boxes among his customers.

"The situation in the market is shown by the following figures, which is the closing price from store: Extra choice, 360s, $7.00; fancy 360s, $7.50; extra fancy 360s, $7.75; extra choice 300, $7.00; fancy 300s, $7.50; extra fancy 300s, $7.75 to $8.00. Such prices for ordinary lemons are unheard of, and indicate the conditions which exist here at present.

"For a week past the weather has been hot and disagreeable. All the influences which usually go to keep it cool and comfortable at this season of the year have temporarily disappeared and humanity is sweltering under an almost tropic heat, with a murky atmosphere that defies one to breathe almost. Such climatic influences are always productive of immense lemon demands. It is impossible to satisfy the requirements of the consumers. They take all they can get and clamor for more. This has been the experience of dealers during the past few days. They have bid prices up at auction to get anything and have seen their supplies actually vanish under the heavy demand from their customers.

A friend of California said that it was too bad that the lemon growers of the Golden State couldn't ship trainloads here now. There would be practically no limit on the price. Consumers would pay whatever was asked for good lemons.

New York.

At Tuesday's auction sale there was not very much interest in oranges and only two cars of Valencias and one car of lemons were offered. Old Mission Valencias were higher and realized better values. A car of Jamaica oranges also was sold and these realized full value. The quality of the fruit was only ordinary, the oranges being immature. One car of lemons was sold and held as high as usual. Grapefruit was in better demand. A few boxes were sold, realizing very fair prices.

The sales showed Old Mission, fancy, at an average of $6.25 per box. The same brand of choice brought $5.25, average. Iris, fancy, D-M Ex, averaged $3.78 per box. Grapefruit averaged about $2.70 per box. Rialto Girl, fancy, lemons, averaged $6.32 per box.

Boston.

At the auction sale Tuesday lemons were steady and firm, selling within a range of $3.60 to $7.55. Valencia oranges brought from $2 to $5 per box. The market was weak at Boston, one car of oranges being withdrawn.

Chicago.

Not many oranges offered. The market was steady and with future demand. Late Valencias, small sizes, brought from $4.75 to $5; large fruit from $4.25 to $4.50. Lemons are selling well even though prices were high. California fancys, sound, brought from $7.50 to $8.50 per box. Limes, per barrel, brought $10 to $12.

California Dried Fruits.

NEW YORK, Sept. 5.—Evaporated apples are without change as far as spot supplies are concerned, though it is reported that prime fruit for future delivery can be secured a shade under recent views. Common to good, 4½@6; prime, 7@7½; choice, 7½; and fancy, 8. Prunes continue firm, on renewed short crop reports and quotations on spot ranged from 4¼ to 7½. Apricots are said to be a shade easier on the Coast, but the local spot market is unchanged. Choice, 8@8¼; extra choice, 8½@8¾, and fancy, 9½@10. Peaches are still firmly held in primary markets, with fancy fruit quoted 11½ in the local market. Raisins are without further change. Loose Muscatels, 5½@7½; seeded raisins, 5¼@8¼; London layers, $1.00@1.15.

Deciduous Fruits.

Deciduous fruit are being shipped east from Sacramento by the California Fruit Distributors at the rate of about sixty cars per day. The prices are holding up astonishingly well. A car from Medford, Oregon, consisting of Bartlett pears, recently sold for $2084. This is the record-breaking sale for the season for a straight car of Bartletts. Three cars sold at Minneapolis Monday for $1194, $914 and $832, respectively. One car at Minneapolis brought $1165. Three cars at Montreal brought $1866, $1833 and $1275. At Pittsburg, two cars were sold for $1365 and $1446. Last Saturday nine cars sold in New York by the California Fruit Distributors. Following are the prices received: Bartletts, $1.90 to $4, average $2.95; Tokays, $1.10 to $2.80, average $1.90; Malagas, $1.10 to $2.25, average, $1.40; Picquetts, 85c to $1.50, average, $1.05; Kelseys, 70c to $1.80, average, $1.60. Market strong.

A CARLOAD OF RUNABOUTS.

The Moline cars which Wm. Gregory has advertised in the Cultivator for some time have proved winners, and many of them have been sold. Mr. Gregory now announces that he will receive this week a carload of runabouts from the Moline factory. These light machines are exceedingly convenient and relable, well made ones.

Any of our readers who may be interested in the automobile will find much of interest in a short talk with Mr. Gregory.

A sure cure for ant troubles is advertised by the Kellogg Ant Paste Co., in this issue. This paste will positively rid your premises of ants. Send for a box.

IN WOMAN'S BREAST

ANY LUMP IS CANCER

Any tumor, lump or sore on the lip, face or anywhere, six months, is cancer. They never pain until almost past cure.

Queries and Suggestions

COVER CROP.

Editor Cultivator: Will you kindly inform me through the medium of your valuable paper which pea is the best to grow as a cover crop where it would be subject to slight frost; also quantity to sow per acre, and the name and address of a reliable seedsman from whom one could purchase seed true to name.—Subscriber, Lindsay.

The peas usually termed the Canadian field pea or the Prussian Blue Field pea, either are used for this purpose, for they stand any ordinary condition of winter growth and give a heavy top and heavy root for plowing under in January and February. This seed may be had of firms advertising such goods in the Cultivator.

DODDER.

Editor Cultivator: Will you kindly inform me through the Cultivator the best way to get rid of dodder in alfalfa field? I sowed forty acres last winter and the seed was very foul with dodder.—John Bell, Long Beach.

It is indeed very unfortunate that you did not screen out the seed before the dodder secured this foothold, because it is most perplexing to eradicate it. Especially, unless you have been very careful to cut this season before dodder has been allowed to go to seed again. Light coating of straw, laid over the affected spots and setting on fire will kill it very quickly, so that if care is taken in keeping the seed from ripening the stuff may be eradicated. The burning of the straw, if not too thickly applied, will not kill the alfalfa.

THE WYOMING DAM.

Editor Cultivator: I see in the Cultivator quite a description of the "Huge Wyoming Dam," and I am interested in it. Could you give me further information about it, or give me the address of some one who knows about it. —S. B. Nobles, Toluca.

Address the United States Land Office, Lander, Wyoming, which will give you further information regarding land underneath the Shoshone dam.

SUN DIAL.

Editor Cultivator: As you prove to be a better source of information than my enclycopedia, I turn to you to learn how to make a sun dial, and how to read it, for a shadow cast on the 12 o'clock mark will not be in the same place next month. In setting up the dial is it necessary to get the exact point of compass by the north star.—J. E. Matthews, Santa Ana.

Sun dials are of various forms and built of various substances, all the way from being carved from the solid rock to being grown on the lawn of variegated flowers. One which we have seen an illustration of consists of a partial circle of light flowers with the figures marked in darker flowers, while the shadow was cast by a mammoth cactus, standing like a trunk of a tree in the center. Usually, however, it is a circular surface erected on a column of stone or other material on which is placed a triangular piece or an arm of metal or wood which will cast the shadow. This arm may be placed directly north and south by sighting on the north star on a clear night or by compass, allowing for the variation, or in any way to be sure accuracy is secured.

From Henderson's Picturesque Gardens, we copy the following:

"A triangular shade finger can be used with the upper edge so inclined that the shadow it casts will reach the same points at the same time daily; this is accomplished by having the upper edge, termed the "time-shadow edge," parallel with the earth's axis, the correct inclination being attained by an astronomical calculation suited to the latitude; or, practically correct results may be obtained by experimenting with a temporary shade finger, say a 3-inch strip of board so arranged that the north end can be adjusted until the correct inclination is obtained; the length of the board should reach about three-fourths of the distance across a semi-circular dial of any desired size. This board (or other shade finger) must run north and south—a compass will aid in setting it true; rest the southern end on the dial surface, then elevate the north end according to the latitude, which is the same as that of Savannah, Ga., will be about 4¾ inches to a foot measured along the ground edge of the shade finger; or for Washington, D. C., 6⅛ inches; for New York City, 6½ inches. The shadow cast by this finger at noon will point directly north toward the location for placing the numerals XII. Compare the position of the twelve o'clock shadow with your watch for a few days, and if it returns to the same position, the proper inclination has been obtained; if the shadow has shifted, then raise or lower the north end of the shade finger as circumstances require, until it casts the shadow continuously right. Then the placing of the rest of the numerals on the dial is simply a matter of noting the location of the shadow at corresponding hours by a watch."

GARDENING QUESTIONS.

Editor Cultivator: Is there a variety of table peas known as Marrowfat? If so, can it be grown successfully in the winter months? What is the time to plant? Average price per pound, yield per acre and are they liable to frost easily?

Would potatoes planted in October or November do well or should I wait until February? Would light frost hurt or kill them?—F. Myers, Ventura.

One of the best peas known is the wrinkled Marrowfat, which is the staple with gardeners. The variety called the smooth Marrowfat is of but little value as a table pea. It can be successfully grown during the winter months, though where there is danger of frost it should be planted early enough that the pods may be set before the danger of frost or else that the blossoms will not come until after the danger of frost. There is in this climate no danger of injury to the vines, only to the blossoms. For the earlier peas, they should be planted in July and if not then planted, at the present time or during the month of October will prove desirable as it will give very early peas in the spring. Another crop may be planted during January for early summer peas. If by price per pound you mean for seed, the best and cleanest seed will command say $5 per hundred pounds. If you mean price per pound of the green product, it varies according to the season and supply from four to ten cents, delivered in San Francisco or Los Angeles. That is, assuming that the stock is clean and desirable. We have seen stock sold in Los Angeles at one and a half and two cents which was badly covered with mildew to the extent that they had turned almost perfectly black. To correct this before there is any appearance of the mildew in the field you should be sure and dust with sulphur. The sulphur usually used is the best grade of flower of sulphur, though some use the ordinary crude ground sulphur.

Potatoes planted in October or November would have to be in a perfectly frostless belt in order to succeed. If such a position is secured they would be exceedingly profitable. Unless such a condition is at command, the February planting, which would give quite early spring potatoes, would be best. The potato will stand no frost whatever, though we have known of cases where the top has been injured by the frost soon after coming up, when planters have gone in with plow and covered the frosted tops entirely with dirt when the seed would sprout again, giving a fair crop.

OUT OF POULTRY BUSINESS.

One of California's largest and most successful poultry breeders announces this week that he has entirely closed out his stock and today hasn't a single bird left. Mr. G. I. Lytle, of Los Angeles, has become interested in that more fascinating, and doubtless more profitable, science of mining and is now digging his gold at first hand instead of feeding it through the poultry. Success to him in his new venture.

Mr. Lytle has been in the business of breeding high grade poultry in California for severeal years and for five years, or within a few days of it, has had his stock announcment in the columns of every issue of the California Cultivator. Mr. Lytle informs us that his use of the Cultivator columns has been most profitable and has brought him more returns than any medium used, though he has used some eight or ten others.

Mr. Lytle has been one of those square, upright breeders of thoroughbred stock which it has been a pleasure to deal with, and the vacancy made by his leaving the ranks will be hard to fill.

COMPLETE fertilizers contain the three essential ingredients—POTASH, phosphoric acid, nitrogen—and they must be in the right proportions to suit the different crops.

We have a book, "Plant-Food," which explains these things fully and interestingly. It is free to farmers—let us send it to you.

The California State Fair at Sacramento

Some Excellent County Exhibits. Fine Showing of Dairy and Beef Cattle, Draft Horses and Driving Stock, Sheep and Poultry

The State Fair at Sacramento last week was not so well attended as it should have been, probably fully as well as it will be for years to come. California is too large a State, the distance too far from one end to the other, to make possible a general attendance from all parts of the State. Certainly the city of Sacramento with its present inadequate hotel facilities, could not care for the people if they should come. It might as well be confessed that the management of the State fair are up against a hard proposition.

That they succeeded so well is due to the fact that the central counties of the State have an empire within themselves. In the south there is another imperial country, while northward lies still another.

So, with all due deference to the powers that be, circumstances make this a district fair, a Sacramento fair, if you please.

When this is said it also follows that the State Society, aided by the progressive citizens of the State capital, made a grand start towards a fair that year by year should grow larger and better. This year the civic organizations of Secramento did their fult share toward providing amusement and entertainment to the many thousands of people who have visited the State fair.

The handsomely decorated streets and lavish displays by both business houses and private residences, the electrical illumination at night, the different parades and the culminating glory of Admission Day celebration, made a combination that brought words of praise from every visitor.

The opening day was Saturday, September 2d, but all the exhibits were not in place before the following Monday. At that time the fair was in full swing and a record attendance was noted for the "first day." This was the day set for the Indian parade, the first of the series, one for each day of the week. Over three hundred Indians, gathered from the hop fields of California and brought from Nevada, were in line.

Tuesday night the ribbon parade by the Sacramento Driving Club was most beautiful, the gaily caparisoned horses, decorated carriages and fashionably dressed ladies and gentlemen passing through the brilliantly lighted streets were heartily applauded all along the line.

The automobile parade Wednesday night was an equally brilliant affair and the Shriners of course made a splendid display Friday. Saturday was "Admission Day" and the general parade under the auspices of the Native Sons of the Golden West was the culmination of the combined efforts of the citizens to give to all a pleasing memory of the fair of 1905.

* * *

The new fair grounds are well out in the country, a good half hour's ride on the electric cars, while the Pavilion is located on the State Capitol grounds. It is a splendid building in the wrong place, amply large for the exhibits—which were not there.

Agricultural products, fruits, mineral exhibits, from a State view-point were lamentably lacking. Excepting for the few county exhibits, the less said the better. In the line of machinery, but for a few local displays, and those of the dairy and creamery people, an equally poor showing was made. In one wing was huddled the poultry exhibit (a new building at the fair ground is promised for next year) and while a few fanciers made a brave effort, the sum total was hardly equal to a good county display.

The chief attraction at the pavilion was the county displays, eight in all. San Joaquin county, through the efforts of the Stockton Chamber of Commerce, made her first exhibit at the State fair and it was a display that did credit to the Gateway county of the San Joaquin valley. Fruits in great variety were displayed, grapes of all kinds, manufactured products, grains, cereals, vegetables, while in the center the figure of a high grizzly bear holding an enormous cornucopia, from which poured a stream of fruits, flowers and products of the county. It was the best and most striking design in the pavilion. Sacramento county, of course, had a fine display in various departments. A very attractive display was made by Yuba and Sutter counties. Here were seen the best results from these two counties. Shasta and Placer counties, also made fine exhibits, while Sonora and Napa were well and fully represented.

In the competition for prizes offered to Native Sons for best displays of products and manufactures in the pavilion the followin awards were made:

San Joaquin County, represented by Stockton Parlor, Native Sons, first prize, $500; Shasta county, second prize, $250; Placer county, third prize, $150; Napa county, fourth prize, $100. Yuba and Sutter divided the fifth and sixth prize, which amounted to $25 each.

With these exhibits eliminated the Pavilion display would have been a minus quantity. One can but wonder how grand and magnificent a display could be made should every county in the State, on some future occasion, conclude to make a county exhibit at the State fair. It would surely make a showing well worth the time and trouble. But it is a long cry from Siskiyou to San Diego and but few could travel the weary miles to attend.

In the Pavilion the dairy separator people were on hand. The De Laval Dairy Supply Co., the U. S. Cream Separator and theSharples Tubular Cream Separator Co., all had representatives present explaining the merits of their respective machines. Here also were th Jubilee Incubator and the Bean Spray pump, of San Jose. Of course no fair could go ahead without an exhibit of the Coulson stock and poultry foods—there is but one Coulson.

* * *

The new fair grounds are farther out from town than the old, but the change was wisely made. Plans were carefully considered and the work so far has been excellent. When in the years to come the grounds are ornamented and all the buildings completed it will be as handsome and convenient a fair ground as one could desire. The one line of electric cars now operating is inadequate during a few hours morning and evening, but this will be remedied.

A splendid race track has been completed, a safe and comfortable grand stand, good buildings of ample size, and plenty of stable and shed room for live stock. The directors of the State fair have earned their meed of praise for what they have done. What has been done gives splendid promise for the future.

The exhibition of stock of all kinds was good. Probably the best, all in all, that has ever been shown at the State fair. In dairy stock and beef cattle, draft and driving horses, imported and domestic, one feels a thrill of satisfaction in seeing so much that is best—so little that would class as merely good. Swine, sheep and goats are here in all breeds and owned by men who know what good stock should be.

In cattle the Shorthorn and Holstein lead in numbers, while the Jersey counts up a strong third. From Washington comes two comparative strangers in California—the Devon and Brown Swiss cattle.

In swine the Berkshire and Poland China were the whole thing—save a fine lot of Durocs. A good showing of Percheron horses was made in addition to the imported stock shown by the large firms of Dunham & Fletcher, Landis Bros., and J. Crouch & Son. Clyde Chipman, of Los Angeles, had a fine lot of Percherons on exhibition and E. F. Kleinmeyer, of the same city, had a fine Percheron stallion which attracted attention.

Among the sheep men, Mr. Glide made a showing of Southdown and French Merinos; Eaton & Shaw, Thos. Waite and J. H. Lynch had Southdowns. Bailey & Co. were showing fine Angora goats.

In the racing programme there were many entries and the afternoons were fully occupied. A sporting friend claimed that the races were "the best ever." Certainly the grand stand had the crowd in the afternoons, while the races were in progress. Human nature is about the same everywhere and it is always the rule for the parents to take the child to the circus to see the animals. Our sporting friend led the child to a fenced off lot wherein there was "hay" for sale. The festive "tiger" lurked therein and pools and strange language were much in evidence. No gambling was allowed, of course, but the tiger was a very active animal withal.

* * *

Down among the stock pens where the Pierce Land and Stock Co. made a splendid showing of Holstein Friesians, was found Mr. Pierce, caught in the act of counting up his ribbons. He had eight gold medals, twelve first, twelve seconds (and five reserve champions) and five thirds—every first and second all along the line. This company had thirty-five head of stock at the fair.

G. A. Murphy, of Perkins, Cal., was showing some fine Shorthorns and Berkshire hogs. P. H. Murphy, of the same place, had some very fine Poland Chinas.

The Howard Cattle Co., the Chowchilla Herd, Isaac Bird, manager, the Humboldt Herd, J. H. Glide & Son and H. P. Eakle, Jr., all had fine Shorthorns on exhibition.

Our old friend, Thos. Waite, of Per-

Selecting Watermelon Seed

By J. C. Ostergard, Burbank, Cal.

A few years ago the Rattlesnake variety of watermelon was the favorite. A great many other kinds were tried, but none could compete until our present melon made its appearance. Before it all the rest, even the favorite Rattlesnake were made to look as third class goods. This, in fact, they were, not only as to appearance but in flavor and sweetness as well. Besides these qualities, it possesses an extra thin rind, making it all meat except for a thin hard shell.

Its origin is shrouded in mystery. I have heard many stories, but all conflicting. It was at first named the Chili melon, then Chilanian, which again was contracted to Chilian, by which name it is best known at present. There is no doubt but that it is a cross, pure and simple, most likely a cross between the Cuban Queen and a small dark melon which the Spanish population have grown for home use for many years, a few patches of which are yet to be found.

This melon has a pure white seed. The Cuban Queen has a white seed with black eyes. There is also a little citron blood in it, just enough to make it a vigorous grower. When first introduced it was badly mixed with various kinds of watermelons, although it was tolerably uniform in appearance. One would meet with white seed, white with black eyes, brown and even black seeds in the same patch of melons, often two kinds on the same plant. The white, however, predominated and today a Chilian melon having other than white seed is not in favor and are not grown much except by careless growers. Yet it must be said that very sweet melons are to be found among those having colored seeds, but in outward appearance, as well as firmness of flesh, none can match the royal, white-seeded Chilian in her dark green, striped, glossy coat. She today stands out the most perfect creation in the watermelon kingdom.

* * *

Seed Selection.—The best time is from now on, the later the better. Most any melon will cut nicely during July and August. It is only the very best that will bear a good eatable melon when the weather turns cool to cold. I would, however, advise everybody not to save their own seed if they are within a half a mile of a patch of citron. Pumpkins rarely mix with watermelons, even if grown among them. But beware of citron. Even if you have no citron near and your own patch is but of indifferent quality, it will be best to buy your seed from some reliable party, who has the best and whom you can rely upon. A pound of good watermelon seed is as easily worth ten dollars as a pound of indifferent seed is worth ten cents. Having satisfied yourself that you can get satisfactory seed from your own patch, select only such as are perfect globes, as smooth of surface as possible and dark green in color, for it is a fact that in as much as the melon tends to lengthen and has depressions over and around the shell it is deteriorating, or running back, as it is generally termed. See to it that your melon cuts clear and has no hollow places between the flesh, is not mealy, is not stringy, and has a thin rind. The flesh must be firm, with seed close to the rind. The flesh should be a bright, clear red. Beware of the copper red color. If the seed is far from the rind, the melon otherwise being fine, don't use it; such seed will produce next year a thick rind melon.

As to size, most any size will do, provided it is otherwise perfect and has grown on a stock having large melons. Yet it is not advisable to use a melon weighing over tweny-five pounds. A melon weighing more than that is apt to be coarse and not evenly ripened. Besides, very large melons are not profitable to the grower. In the Southern States, where the temperature is high, day and night, very large melons ripen to perfection, but here, where we have warm days with cool nights, the melons don't get heated through when very large. Our very best melons weigh from twelve to twenty-five pounds.

* * *

THE SELECTION OF CANTALOUPE SEED.

This is a very easy matter. Just observe that they are well netted, possess but a small cavity and are otherwise perfect. Place the seed in an ordinary bucket and churn with a wire potato masher until the seed are all free of the stringy matter. Strain and pick the stringy stuff off by hand. Dry in the shade, as sunlight weakens their vitality. Don't save your own seed unless you are far from cucumbers, pumpkins, squash and other varieties of muskmelons.

* * *

TOMATOES.

The unusually cool, moist spring and summer has been highly favorable to fungus growth. As a consequence tomatoes have suffered as never before. Fully seventy-five per cent have blighted. Against this plague has been applied every remedy known as a fungicide. The result has not been attended with even partial success. Indeed the results have been absolutely nil. Fields everywhere have been afflicted, now fields have not escaped. I have had a good chance to observe its peculiarities in a field of forty acres that has been in water and muskmelons for several years. I have replanted the wilted melon vines with tomatoes. Being a mesa just at the base of the mountains, there is a good deal of variety of soil. In spots it is sandy soil underlaid with loam. Fully ninety-five per cent died long ago on the dark loam where the heat is greater than on the white, or partially white sand. There is at present remaining about forty per cent, most of these have grown but little until the recent hot weather, but since then they have grown fast. Heat will kill fungus at a temperature of about one hundred and thirty-two degrees Fahrenheit. On a hot day, with the temperature at ninety degrees in the shade the average mesa soil will be found to have a temperature of about one hundred and thirty-eight degrees, or more than enough to kill the fungus. Accordingly, it is well to wait and not plant fall or winter tomatoes until after a real hot spell and then dust the plant and soil around it for a foot on all sides with sulphur. After the disease is contracted neither heat nor fungicides are of any avail. As the ground is now likely to be free of the pest, I would advise replanting with the winter sorts, Atlantic Prize and Early Richmond being the favorites. But it should be done at once and only in the frostless regions.

* * *

Early Rose potatoes, if planted now, in the frostless belts, will come in as "scrapers" for the Christmas trade, at which time they usually bring three cents a pound.

* * *

Plant Yorkshire Hero peas now only in warm sections.

Plant your last crop of beans now, but only in warm sections.—J. C. Ostergood, Castle Cove, Burbank.

* * *

[A few ideal watermelons grown by Mr. Ostergood may be seen at the Los Angeles Chamber of Commerce.]

BEES AND ANTS.

Strong colonies usually protect themselves from ants. If quilts are used, discard them and allow the bees free access to all parts of the hive. If black ants, hunt up their nest (which is not far away), make a hole in its center, put in one-half pint bisulphide of carbon, close up hole with wet mud and dampen ground around nest. Be careful to keep the drug away from fire.

Another way to destroy ants is to mix flour with honey, adding arsenic or Paris green, making a paste. Then on two boards of equal size nail a piece of section on each corner of one, spread the paste on it and use the other for a cover, fastening both together so that nothing except ants and like insects can get between. The piece of section is just the thickness to allow ants to enter, but keeps bees out, the ants carry the poisoned food home and feed it to their larva with good results—to the bees. Still another way is to place the hive on four feet set in pie tins filled with coal oil; ants will not cross the oil to reach the hive. It may not be out of the way to repeat that strong colonies are the surest preventives of many of the ills of beekeepers.—W. S. & H.

BEES AND THEIR WAYS.

Bees are very uniform in their actions, they do things after a certain manner as I suppose they have been doing them for ages past. An intimate knowledge of their habits enables the skillful beekeeper to control their actions to suit his purpose. He does not seek to change their instincts, but only to take advantage of them.

I will mention a few of the habits that have been turned to good account in the evolution of modern beekeeping.

It is the rule for bees to build their brood combs of a uniform thickness and a certain distance apart. It was found by measurement that bees, when left to themselves, space their combs one and one-half inches from center to center. Then it was that men, noticing this rule, began to try to devise some means to bring the manipulation of the combs within easier reach. At last Langstroth brought out, or at least, perfected the movable frame, by means of which the combs of a colony could be easily removed from the hive for examination; could be transposed, or exchanged with the combs from another hive. If it had not been customary for the bees to build their combs straight and uniform, men would not have thought of having the combs built in frames.

A normal colony of bees casting a prime swarm uniformly takes its reigning or laying queen with said swarm, and the swarm will alight and hang in a cluster before leaving for their final home.

Taking advantage of this habit, the practiced beekeeper does not go to the trouble to beat tin pans and throw dirt in the air in order to stop such a swarm. He knows they will first cluster on some tree or bush and while thus clustered he will have time to prepare a hive for their reception. If they take flight from the cluster he knows they will leave for parts unknown and it is then that he will resort to any and all means to stop them. My method of stopping run-away swarms is to avoid ever having any.

A normal swarm of bees will uniformly return to the hive from which they came if by any chance the queen is not with them; taking advantage of this fact we clip off a part of one wing from the queens before swarming season begins, then when the swarms issue the queens not being able to fly, are found and caged at the entrance, and held till the swarm begins to return, when they are released and allowed to run in. In the interval that the bees are in the air before discovering the absence of the queen the hive can be taken away and a new one put in its place. To this new hive the bees will return because it is a law with them to return to the old location. Now you begin to see how a knowledge of these things aids us in the practical work of the apiary. If bees begin to build a comb straight they will finish it that way. We therefore, place strips of foundation in the frames or section boxes, it having been demonstrated that the bees will uniformly start their comb on these thin strips of pressed wax.

Every beekeeper knows that bees will pounce on any exposed sweets during a dearth of honey when bees can not find nectar in the flowers, and that they will become very much excited and will be likely to enter other hives than their own for the purpose of robbing and will sometimes become angry and sting stock or passersby. He will therefore carefully avoid exposing any bits of honey or other sweets at such times, and women preparing preserves should do so behind closed or screened doors. If not she may be bothered by having a lot of bees buzzing inside of her kitchen. At a time when there is honey in the flowers, bees do not notice any such exposed sweets.

As a rule bees cast a prime swarm as soon as the first queen cell is sealed, unless prevented by bad weather, therefore the first young queen may be expected to emerge on the eighth day from the first swarm. When the young queen hatches we may look for a second or after swarm. Knowing this law we will look in the hive on the seventh day and destroy all but one queen cell. There will be no swarm in accordance with another well known law that the bees will not leave the hive queenless and no provision for a new queen to be reared. It will be seen that beekeeping consists in conforming your methods to the habits of the bees in such a way as to have them do your will by not willing that they shall do anything contrary to their established customs.—Wisconsin Agriculturist.

Sheep greatly improve land when too many are not kept on an acre.

PROVIDE PLENTY OF ROOM.

When honey is coming in freely bees ought to have plenty of room to store it. They need looking after every few days, and if they have a case of sections on don't wait until they are all full before giving additional room. Farmer beekeepers often neglect to provide sufficient supers and sections to obtain the best results from their bees. That is one reason why the bees swarm so much.

My own practice is as follows: I try to get the supers on before the bees make preparations for swarming. When work is nicely begun in the sections—say three-fourths finished—we lift the super and slip an empty one under it—if honey is coming in. Of course, this practice is not for the close of the season, but for the honey harvest, no matter from what source it is derived. That provides for the finishing touches to be put on the comb always at the top, as far removed as possible from the brood combs and the soiling which is liable to be seen on cappings if close to the brood nest; and the top of the hive being the warmest spot it is the ideal place to ripen the honey and improve its quality. Some people take the surplus off as fast as it is finished. This is all right if one needs to use it, but I have never found a place quite so nice in which to keep honey in all its richness during the summer, as in the hive. If tiered up as I suggest, the honey will not be stained by the bees traveling over it to its injury, and its quality will be greatly improved.

A good colony ought to store more than one super full during the season. In my own yard it is not uncommon to see them piled four high. If one waits until the first super is completely filled and capped before supplying additional room, the brood chamber is likely to be filled also with honey instead of brood, and it is plenty of brood that we must have if we are to get large crops of honey. Give them plenty of room.—N. W. Agriculturist.

INSTANTANEOUS LIGHT.

You can have your bee smoker lit in two seconds ready for use by buying half a pound of saltpeter and dissolving it in three pints of water. Then get any old cotton rags and cut in thin strips not more than one inch wide, any length. When the saltpeter has all dissolved put in your rags and let them stay in till they are well soaked. Then hang up to dry. Be careful not to dry by the stove or they may cause a fire. When you have them thoroughly dry cut up into lengths of about three inches. Keep in a tin pail with a good tight lid. One of these strips is enough to start your smoker. It is instantaneous, never blows out in the strongest wind and is always ready to use. You don't have to run in the house to the kitchen stove and bother the women folks.

Mrs. Hi Flyre—They say that Mrs All De Mustard's beautiful house is simply crowded with Murillos and Velasquezes. Mrs. Justin De Bunch—Mercy! Has she tried pouring gasolene in the cracks and fumigating with formaldeheyde?—Cleveland Leader.

Edges That Last

Probably you have bought edged tools made of steel that was crumbly, or too soft to hold an edge, or so hard as to be brittle. You may have bought them for good tools, too. There is, however, a sure way to get tools with edges that last. It is simply to ask for the Keen Kutter Brand when buying. Keen Kutter Tools have been standard of America for 36 years, and are in every case the best that brains, money and skill can produce. They are made of the finest grades of steel and by the most expert tool makers. As a complete line of tools is sold under this brand, in buying any kind of tool all you need remember is the name

KEEN KUTTER

The draw knife shown here is an example of the excellence of Keen Kutter Tools. It has a nicety of balance and "hang," which has never been successfully imitated, and it is made of the best steel ever put into a draw knife. In all the years that we have sold this tool we have never heard of one defective in any way.

Yet the Keen Kutter Draw Knife is no better than all other Keen Kutter Tools.

The Keen Kutter Line was awarded the Grand Prize at the St. Louis Fair, being the only complete line of tools ever to receive a reward at a great exposition.

Following are some of the various kinds of Keen Kutter Tools: Axes, Adzes, Hammers, Hatchets, Chisels, Screw Drivers, Auger Bits, Files, Planes, Draw Knives, Saws, Tool Cabinets, Scythes, Hay Knives, Grass Hooks, Brush Hooks, Corn Knives, Eye Hoes, Trowels, Pruning Shears, Tinners' Snips, Scissors, Shears, Hair Clippers, Horse Shears, Razors, etc., and Knives of all kinds.

If your dealer does not keep Keen Kutter Tools, write us and learn where to get them.

Every Keen Kutter Tool is sold under this Mark and Motto:

"The Recollection of Quality Remains Long After the Price is Forgotten."

Trade Mark Registered.

Outlook for Citrus Industry

A Pilgrimage by a Cultivator Writer Finds a Hopeful and Healthy Feeling Amongst the Orange and Lemon Growers

The closing of the present citrus season is so much different than it was feared it would be that there is a general feeling of satisfaction in nearly every citrus growing section of California. Of course, even earlier, the citrus growers of the Tulare section, which markets nearly all its fruit for the holiday trade, felt that they were well out of the woods in that the prices of the holiday season, which are almost invariably satisfactory, had put them out of reach of any slump which might come during the heavier shipping season, when the Southern California production seeks its market. Out of the total of over thirty thousand carloads of citrus fruit, the Northern California growers have but about fifteen or sixteen hundred cars, and, owing to the warmer summer season, their fruit is almost invariably well colored and well sweetened for the holiday trade, so that the trees are entirely clear before the first of January. The great bulk of Southern California shipments does not begin until well into January and that season is no more fully on than the orchards in some sections begin to show a tendency to drop some of the fruit and, possibly, as in the case of this year, a percentage of "puffs" appear. This has a depressing effect upon the growers and creates a desire to move just as much of their fruit as it is possible to induce the buyer or the packing house management to take. If the locality where such fruit is grown was comparatively limited, there would be no serious effect upon the market, but owing to the great quantity, there is some danger of deteriorating, or which the growers feel may deteriorate, the pressure becomes almost unbearable and the various shippers sometimes forward more than their best judgment dictates and than the market will absorb.

We would not, however, carry the idea that the low prices of last midwinter were entirely due to this pressure and overshipment. For eastern weather conditions doubtless had more to do with the low price than any other one feature. With the thermometer registering way below zero, it became not only impossible to display fruit upon stands and in peddlers' carts, but even absolutely unsafe to open cars at auction houses. Such a condition prevailed over a large territory of the East for weeks at a time and it was a condition which could not be anticipated, so that the large number of cars of fruit in transit only continued to pile up and remain in storage until the weather moderated. Besides that, another condition which effected seriously the selling price, was the poor keeping quality. Possibly owing to the warm, moist season, the flow of sap began much earlier than usual and that is a condition of tree well known to endanger the carrying quality of oranges. In any case, it is certain that at the breaking up of the cold eastern weather there were not only a large number of cars in storage showing some decay from long holding, and, in addition, vast numbers of other cars arriving showing a large percentage of decay in transit. Therefore, the prices received for the growers during the months of January and February may be said to be exceedingly unsatisfactory.

This unsatisfactory price is especially true in cases where the shipper pooled or bunched nearly all his fruit in those months. The larger shippers, or the members of co-operative organizations which pooled fruits during the entire season, will receive a fair average. We think it is safe to say that all citrus fruits shipped out of California during the season will average well up towards $500 per car. At least, that is the statement which the Exchange makes, that its entire shipments will make that average. Of course, this included Valencias and lemons, which have had an exceedingly good price during the entire summer. There are, however, some shippers who claim for navels alone, in excess of $450 to $480 per car for the season.

Those prices per car are, of course, f. o. b., so that the grower will not net quite those prices. The cost of packing and marketing will vary from say 27 cents to 40 cents per box.

Valencias and lemons have commanded the highest prices during this summer which they have ever reached, that is, the highest general average. Take lemons for instance. Mr. Dreher, of Pomona, recently informed the Cultivator, that the San Dimas Lemon Union had aggregated over $60,000. for sixty consecutive cars of lemons. Many individual cars have reached to the maximum of $1600 and $1700, but for an aggregate on that number of cars we do not think that amount for sixty consecutive cars from one house was ever received before.

Valencias have aggregated $2200 and $2300 a car f. o. b. eastern points, which, for oranges, is simply immense, and while all Valencias have not reached such prices, the average has been very high, say $2 to $4 per box to the grower.

These points are mentioned to call attention of the growers to the fact that this season has not been so disastrous as is often imagined. During the earlier season when for a time the prices were disastrously low, which gave such a depressed feeling that by its very inertia remains with the mass of the growers until this day. But that that feeling is not justified by the facts we believe a careful survey of the situation will convince anyone.

To that end the Cultivator has devoted considerable time visiting nearly every citrus growing section south of Tehachapi. While we find it impossible to get exact figures as to season averages, yet many interesting points have been learned which will be the basis of an article or two which we trust will have much of interest to citrus growers.

A consignment of about fifty thousand young rainbow trout arrived at Redding last Saturday from the Sisson hatchery for distribution. in the streams of that county.

The Santa Fe road is running a special express car for the grape trade from the El Cajon valley.

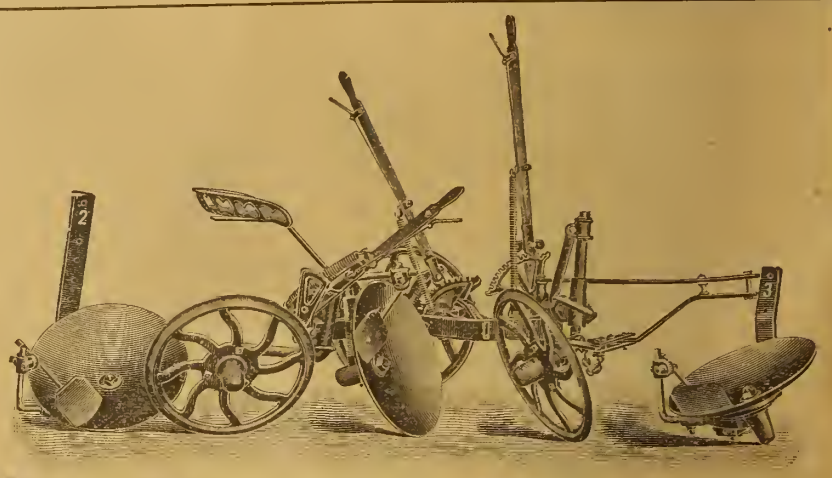
THE BEST EVER

The California Limited Log-Book:

The California Limited is the finest train in the world, and as for service, it can't be beat.

JOHN McDYER,
Chicago, Ill.

SANTA FE IS THE WAY



The Emerson Disc Plow

Has distinctive features over every other make. The levers are controlled from the seat. Turns a square corner to right or left. Width of cut controlled by operator or team.

Slant of discs adjust the plow for either sandy or gumbo soil. **It has many other features** which make it easily the leader of its class. Instantaneous acting lever. Each plow convertible from 1 to 2 or 3 discs or reduced from 2 or 3 to 1 by a very simple manipulation.

The bearings are absolutely dust proof and oil tight. The discs run on adjustable and oil retaining ball bearings.

Rear lever provides ample depth of furrow in opening land and when on the road.

It is compact, strong, durable and **light draft.** By using a disc plow in the early fall the farmer can get a distinct advantage from the early rains. **The Emerson Disc Plow** is a leader in its class and prospective purchasers should investigate its merits.

Read these testimonials and then judge for yourself:

El Monte, June 8, 1905.
I have used your Emerson Disc Plow in salt grass as well as in all kinds of soil and under all conditions, and I have found it entirely satisfactory in every respect.—P. C. CARLILE.

Los Angeles, June 8, 1905.
Your Emerson Disc Plow has given entire satisfaction in dry and wet plowing. It has no equal; also is the best plow I ever used on weedy lands.
E. L. WALDRON.

June 8, 1905.
I have an Emerson Disc Plow, 1904, I bought to plow black adobe hills and found her the best I have ever seen. Some of my adobe is like iron when it is dry and she did good work. I could plow eight inches deep with a three gang, five horses.
DAN McCONAUGHY.

Fullerton, Cal, June 8, 1905.
The Emerson Disc Plow we have used on our farm at La Habra, Cal., for one season, 1905, and find that it is superior to any plow we have ever used; that it will side hill ground where no other disc plow will work and will not upset; that for high weeds it has no equal that we have ever seen work, and will turn the weeds completely under the soil; and for changing into different classes from one to two or more discs, it is ahead of any plow made. A. C. SWEET.

Pasadena Sewer Farm,
June 6, 1905.
I hereby certify that the above picture of the Emerson Disc Plow was taken on the Pasadena Sewer Farm, and that it shows the true condition of the crop of weeds that I plowed under. I used 4 mules on a 2-gang plow and plowed 7 inches deep. I further state that I have given the plow a thorough test in all kinds and conditions of soil and that it has given thorough satisfaction. L. O. McGREW, Supt. Pasadena Sewer Farm.

We sell these very satisfactory plows. You make no mistake in purchasing of us. Our catalogue gives a full description of the **Emerson Disc Plow**, together with many other farm implements and utilities. **It is sent upon request.**

CITRUS FRUITS

By C. A. Day. Pasadena

PARASITE FOR PURPLE SCALE.

In the Cultivator of September 1st Mr. John Isaac writes that "Compere, during one of his visits to China discovered an effective parasite for the purple scale, and an effort made at that time to introduce it into California proved a failure, but that a new effort is now being made by sending California orange trees infected with purple scale to China and when the scale is parasitized the trees with their scale will be forwarded to San Francisco where every preparation will be made to receive and breed them for gneral distribution." I believe the above statement to be correct and while no mention is made of who has arranged and is carrying out this later plan of sending infested trees to China, it will generally be understood by the readers of the Cultivator that it is the work of the State Horticultural Commission. It is another case of one of the county horticultural commissions co-operating with the State commission in the work of insect control, and credit should be given to the Horticultural Commission of Los Angeles county for conceiving the plan of placing potted orange trees in close proximity to orchard trees infected with purple scale, and when thoroughly infested these trees, four in number, were forwarded to the State Commission for transportation to China with the agreement between the county and State commissions that two of the trees on their return should be turned over to the Los Angeles Commission as their share in the venture.

The Los Angeles Commission was prompted to take action in this matter because of the expensive and almost hopeless task of fighting the purple scale in a certain district of the county.

* * *

RED SPIDER.

The red spider or mite which attacks citrus trees and their fruit has proven itself worthy of careful attention. These mites are found located on the leaves, wood and fruit. They feed by sucking, pumping out the liquid parts of living cells and the chlorophyll or green bodies suspended in them. The leaves turn white and are finally killed and fall to the ground. The bare wood of the twigs thus denuded of leaves die, and the effect on the fruit is to cause it to drop.

The spiders are often found in large numbers on the fruit of the orange and lemon, and we have good reason to believe that they impare the keeping qualities of the fruit. Some years ago a severe attack of spiders in the month of March on the orange trees of the Nelson Bailey orchard at Alhambra caused the dropping of 2000 boxes of oranges. Tests were made of this dropped fruit as to its keeping qualities, and it was found that the fruit began to decay in a very few days.

* * *

When the Mites are Most Injurious.—The mites work, and breed to some extent, at all times of the year, whenever wet weather does not interfere. We find them at work during the warm, dry periods of the winter season—and through the spring, summer and fall, but the spring and fall seem to be he times of their greatest activity. The most evident injury is during the months of October and November, when they cause the leaves and fruit to drop. They are spasmodic in their appearance and frequently appear suddenly in great numbers, causing serious injury in a few days' time, and then as suddenly diminish in numbers and continue with but little apparent injury. In many cases the leaves of the trees change in color from green to gray caused by the mites sucking the juice of the leaf and with it the chlorophyll or green coloring matter of the leaf. This interferes with the digestive functions of the tree and while the leaves do not immediately drop, they are of but little use in taking the carbon dioxide from the atmosphere.

* * *

Failure to Apply Remedy in time.—In very many cases the orchardist fails to apply the treatment to the spider in time to prevent injury to the foliage and fruit of the tree. Where the orchardist waits until the tree and fruit show signs of injury and the leaves and fruit begin to drop, the principal damage will have been done before a spraying machine can be procured and the orchard sprayed. A careful watch should be kept of the increase of the spider and whenever there is a large increase of eggs on the leaves and fruit the treatment should be applied at once. By the aid of a magnifying glass the eggs will be found as little blood-red dots on the upper side of the leaf lined up along the central rib of the leaf and will also be found on the wood and the fruit.

* * *

Remedies in Use.—Fumigating has no effect on the mites. Distillate mechanical mixture is very much used as a remedy jointly for both the mites and black scale. Dry sulphur is sometimes applied to the trees when the foliage is damp, but this way is not as thorough or effective as when mixed with water, using a little wheat flour as a paste to fasten the grains of sulphur to the foliage and wood of the tree. As the sulphur does not go into solution, the mixture must be kept stirred so as to keep the sulphur suspended. Power sprayers with agitators are commonly used. The proportion of this mixture as used by some sprayers is 100 gallons of water, 11 pounds of sulphur, 4 pounds of wheat flour first made into a paste, free from lumps, and one pound of lime slacked and strained. The lime is used to neutralize the acid in the sulphur.

The fumes of the sulphur arising from the action of the sun destroys the living spiders and will continue to act until all the eggs are hatched, making clean work. In some cases liquid sulphur is used to spray for red spider. The proportion as given is 10 pounds of caustic soda (98 per cent), 20 pounds of sulphur and 20 gallons of water, forming a stock solution, one gallon of this stock solution to 80 gallons of water. The caustic soda liquefies the sulphur, making a perfect solution.

Personally I have had no experience with this solution, but it is said to be effective. I have seen cases where the fruit was injured or burned, presumably because of a failure to make a perfect solution, or from too great a proportion of the caustic soda.

By some sprayers the liquefied sulphur is preferred as it does not clog the spraying machine as is sometimes the case with the sulphur and paste mixture.

The latter mixture, counting the cost of material, labor of mixing and, sometimes, trouble in clogging of the spraying machine, is the more expensive.

The distillate mechanical mixture is preferred by many growers because of its cheapness and that it is in a measure effective on both the spider and the black scale.

The distillate is not as thorough in its effect on the spider and their eggs as the sulphur mixture, but it will temporarily hold the spiders in check, but in bad cases will require more than one treatment during the season. I have said that the spider is spasmodic and irregular in its attack on citrus trees. Some orchards have a good stock of spiders every year and require treatment. Other orchards, even when not treated, suffer but little injury. From observation it seems as though the spider worked more freely on trees practically free from black scale. It is supposed by some that the fungus accompanying the black scale in some measure interferes with the work of the spider.

* * *

FUNGUS FOR BLACK SCALE.

In the Cultivator of last week Dr. S. M. Woodbridge writes of the fungus which destroys the larvae of the black scale, while it is yet under the shell of the old scale.

I have observed in many cases what I supposed to be the effect of this fungus in destroying the larvae of the black scale. I find the shell of the old scale full of dead larvae of the scale. But it does not destroy the larvae of all the scale on the tree. It would be of interest if Dr. Woodbridge would give us the condition most favorable for the growth of this fungus and what effect moisture and climatic conditions would have in its propagation.

A hot, strong lemonade taken at bedtime will sometimes break up a bad cold.

BY ERNEST BRAUNTON, LOS ANGELES, CAL.

VALUE OF PERENNIALS.

In gardens where only a limited care can be given, those that are occasionally neglected for a time, the use of perennials will give much better satisfaction than any annuals. Perennials root deeply in the soil and most of them have a fine system of fibrous roots, often running into thousands on a single clump of plants. Such an arrangement well fits them for successfully enduring drought and periods of neglect. Good care must be given the first summer, however, to ensure the proper development of a feeding system. If more of these old fashioned perennials were used we would hear far less about having "no flowers in summer," and "our garden is so bare of plants during hot weather."

The following is a list of such plants as are used for such purposes as above stated. Some of these plants have annual sorts, but you must, in ordering, get the perennial species. Asters, candytuft Canterbury bells, corecpsis, geraniums, petunia, phlox, poppy, rudbeckia, sunflower. The perennials among the asters, sunflowers, etc., are not so large and showy as the annual species but are, as a rule, easier to grow and their permanence makes them extremely desirable as compared with the annuals. Those grown from seeds may be planted now. Plants may be put in whenever procurable

CARE OF PANSIES.

A Riverside county correspondent asks: "When is the best time for sowing pansy seed, and how to sow and care for same?"

The time to sow pansy seed is now. The best plan is to sow in shallow boxes three to four inches deep, not so tight but water can run through bottom. Fill with sandy loam, press soil down gently with your hands or block of wood, sow seed evenly over the surface and cover very lightly with soil. Never allow the surface of the soil to get very dry, neither keep it in a soggy condition.

Keep on the shady side of the house and when plants are one-half to one inch across, plant where needed in a rich, friable loam and keep well watered and manured until well in bloom, when the fertilizer can be withheld. If boxes are not to be had for starting the seeds, a shady spot at the side of the house will do, provided the soil is easily drained. As these plants are for winter and spring flowering they should be planted largely in the sun, though they will flower in almost any locality sooner or later. Pansies are perfectly hardy anywhere on the Pacific Coast. The hot sun of summer is what they cannot endure. If planted for summer they should be put on the north side of buildings or trees, shrubs, etc. The flowering season may be greatly prolonged by keeping the old flowers and seed capsules picked off.

COLUMBINES.

Columbines will grow almost everywhere and they should be found in every garden, for their blooms are invaluable for cutting. The columbine is a most desirable plant in all its varieties. It forms a large clump, blooms long and abundantly and is elegant in habit. The seed may be sown in the open ground, preferably where the plants are to grow, and they should be thinned to a foot apart, or to secure a good display of flowers the following season they may be sown in the fall, or good clumps of seedlings may be planted at that time. Most of them thrive with ordinary garden culture. The varieties coerulea and chrysantha do best in well drained, partially shaded spots.

Aquilegia coerulea, the Rocky Mountain blue columbine, is called the finest of all, its sepals dark blue and petals white. Chrysantha has golden yellow blossoms, with very long spikes. Skinneri, the Mexican columbine, is very handsome and quite distinct, the spurs and sepals long, crimson and light green.

There are also many beautiful hybrids in pink and white, mauve, creamy yellow and pure white, which are quite as lovely as the typical plants. We have one species quite general throughout California in the coast mountains, A. truncata, having scarlet flowers tinged with yellow.

THE CRAB'S EYE VINE.

About fifteen years ago M. Nowack, an Austrian, described a "Weather plant" supposed to have been discovered by him. The plant in question proved to be what is known in the West Indies and elsewhere as the "Crab's Eyes." It is a slender vine with pinnate leaves, producing small, bright-red seeds with a black spot. The scientific name is Abrus precatorius. The first name was given on account of the softness of the leaves, and the second (prayer or paternoster pea) because the bright-colored seeds were sometimes used as a rosary.

M. Nowack claimed that by closely watching the changes that took place in the position of the leaves and the rise and fall of the twigs and branches he could predict "changes in the weather and also the occurrence of earthquakes." After a full and careful investigation made at Kew and elsewhere, Professor F. W. Oliver was in a position to show, conclusively, that the "Crab's Eyes" plant only exhibited the usual sleep-movements commonly noticed in tropical vegetation and that there was no connection existing between these movements and the changes of the weather or the occurrence of earthquakes.

This vine is quite common throughout California and has been watched during changes of weather by many interested persons, but no one has been able to notice any change in the plant other than comes to many under like circumstances. We find altogether too many "wonderful" plants in the seed catalogues of the present day.

THE FORSYTHIA.

The Golden Bells or Forsythias are very well known from their brilliant yellow flowers which lighten up the shrubbery in the earliest days of spring. They are amongst the most highly ornamental of our shrubs, remarkably free flowering, and later, when the leaves appear they form handsome bushes with clean foliage, unusually free from pests or disease. They grow almost anywhere, but given a rich soil their luxuriance is really astonishing. There are several forms in cultivation, the commonest of all belonging to two species, viridissima and suspensa.

The garden forms known as Sieboldi and Fortunei are varieties of the latter species, which is one of the most beautiful shrubs for the margins of groups, as it forms a perfect mantle right down to the ground. The tips of the shoots will take root in the ground, and thus perfect thickets can be obtained from one original plant. The plant grows six to eight feet high. The variety Fortuni is more vigorous than the type, while Sieboldi is very slender. F. viridissima grows with an erect habit and the flowers are not so purely yellow. Another form often confounded with suspensa is F. intermedia, a hybrid between the two other species; it is very free flowering, has flowers like those of Fortunei and resembles the other parent in its foliage. In the south end of our State these shrubs do best in partial shade, north slopes or exposures, growing best under the influence of sea breezes. Farther north they seem to thrive much better and will stand more exposure to the sun.

General Agricultural Notes

SULPHUR AND POTATO SCAB.

The Rural New Yorker thus answers an inquiry as to the use of sulphur and formalin for potato scab: "We have used sulphur for some years, both alone and in connection with soaking. For preventing scab we do not find it equal to soaking, but we are satisfied that it sometimes prevents rotting of the seed, especially in wet soils or cold, damp season. Formalin is better than corrosive sublimate for soaking the seed. You can use one pint of formalin in thirty gallons of water. We would rinse off the potatoes before soaking and let them stay in the liquid two hours. They will not be hurt unless the sprouts are very far advanced.

"The same liquid can be used again and again. After taking out the potatoes, dry them and cut. We use peach baskets for this purpose, scattering sulphur over the seed from time to time, and shaking the basket so that the sulphur sifts down through. The basket should be used the second time. The true scab is a skin disease which spreads by means of tiny germs.

"The object of soaking or using sulphur is to destroy the germs on the seed without hurting the sprouts. Of course a liquid would be more likely to destroy all these germs than a powder would. There may be germs in the soil. In such case the crop might be scabby even though all the germs on the seed be killed. This will explain the matter to some who cannot understand how there could be scab on the crop if the seed is thoroughly soaked.

"In some cases sulphur has been scattered in the hill or drill with the seed, and this has given clean tubers even when it was known that a scabby crop grew there the year before. We have found that the sulphur preserves the seed. In some cases we have found the piece of seed with the sulphur still on it at digging time."

ADVANTAGE OF THE SILO.

After referring to the advantage of ensilage as a feed the Western Farmer and Dairyman gives the following good points:

A cheap improvised silo will be a failure and is not to be recommended. The most approved and satisfactory silos are those which are built round, the height should be at least twice the diameter. Any durable timber will answer the purpose for silo building, the inside surface should be smooth. Two by six plank are commonly used, either square edged or with tongue and groove. The bottom is ordinarily prepared by excavating and building a stone wall laid in cement. There is no objection to having this excavation three or four feet deep, it is not necessary, merely increases the capacity of the silo, the wall should be one to two feet above the surface. On this the staves are set up on end and held in place by five-eighths inch round iron rods, wire cables answering the same purpose, securely fastened with lugs and screw nuts. The hoops at the bottom should be placed about two feet between each other, the distance may be slightly increased after passing the center of the height of the silo; at or near the top they may be two and a half or three feet apart. Any kind of a roof that will keep out the snow and rain will answer. Doors are cut at intervals of three or four feet to facilitate the filling and particularly to get the ensilage out for feeding purposes. The filling is rapidly done. An ensilage cutter and some kind of a power are necessary. At the present time gasoline engines are preferred—eight or ten-horse power would be a good size. In securing a cutter be sure and get one that economizes in power. You can either use a carrier or a blower; the latter are considered preferable, yet there are those who cling to the carrier.

It is generally conceded that the best time to put corn into the silo is when it begins to glaze. It should be cut and drawn from the field, run through the silage cutter and made into lengths varying from ½ to 1½ inches, the shorter lengths preferred. If the corn is pretty dry add a few pails of water to each load. If in good condition this is not necessary. It is very important to tread thoroughly around the outer edges, as it is a necessary feature to have it thoroughly packed. Keep the center higher when filling, so it will settle toward the sides and not away from them. When the silo is filled it will in a short time settle a number of feet, and can be filled again after a few days. At the final filling it may or it may not be covered at all, but expect to lose a few inches of silage on top.

The feeding of silage properly stored in a good silo to dairy herds has been a pronounced success. It is not only one of the best but cheapest feeds that can be produced. There is every reason for believing that with the same acreage double the number of stock can be kept, and especially in the case of milk cows a large increase in the flow may be expected. The feeding of silage to sheep and all kinds of horn cattle has been highly satisfactory. About forty pounds daily is a good ration for a cow. If the corn is very heavy, feed less and supplement it with alfalfa.

QUALITY OF POTATOES—SUMMARY.

The salient and practical lessons to which the study of soil climate seems to point may be briefly summarized as follows:

1. Tubers grow out upon a short stem or stalk from the plant stem at regular nodes above the planted tuber. It is therefore necessary to plant five or six inches deep (in good soil) in order that the plant may have room enough to form nodes to accommodate the tubers which it is able to bear.

2. If planted deeper than six inches the moisture and temperature conditions are unsuitable for the development of the tubers on the first one or two nodes. The tubers are of under size, immature, and somewhat prone to scabbiness.

3. If planted shallower than three inches, the variations in temperature and moisture is too great for proper development. The tubers are crowded, and there is a large proportion of small, compound, exposed and scabby tubers and also a tendency to produce tubers on the stalk.

4. Tubers growing between the depths of one and one-half and four inches are of more uniformly good quality in appearance and cooking, in good size, and good development, than those growing deeper or shallower.

5. Long tubers which grow sloping in the ground will show a difference in cooking qualities (mealiness vs. sogginess) between the bud end (end nearest the surface) and the stem end. The stem end cooks more mealy. In most of such instances the stem end is netted, while the bud end has a smooth surface.

6. Though it cannot be said definitely, it is believed that good quality is developed under a uniform soil temperature of 65-75 degrees. Tubers growing one and two to five inches below the surface are subject to these conditions. Great fluctuation in temperature is detrimental to the best development of potatoes. Tubers growing above the one and one-half inch level are more or less subject to this fluctuation. Uniformly low temperature below 65 degrees is not conducive to the best development and ripening of the tubers. It may bo also that soil texture has an influence on these favorable and adverse conditions.—Desert Farmer.

INTENSIVE FARMING.

As a lesson to American farmers an exchange says:

Japan contains about the same area as Great Britain, with considerably more inhabitants. Yet she produces all the food required by her people and exports a large quantity in the shape of rice, whereas Great Britain imports foodstuffs to the amount of hundreds of millions of dollars.

The secret of this wonderful difference in favor of Japan is to be found in the greater knowledge and skill of her farmers in the promotion and preservation of fertility. The Japanese farmer would be horror-struck at the idea of cultivating the soil to the extent of reducing its fertility. The American farmer outdoes the English farmer as a soil waster. There are large lessons here.

Milk which stands too long makes bitter butter.

WANTED

To rent on shares or for cash the best sandy sediment cantaloupe and early grape land, located at Brawley, Cal. Will furnish seed or grape vines, land, water and everything except labor. Will rent in any sized tracts for a term of years. Get full information from

Imperial Investment Company
315 H. W. Hellman Bldg. Los Angeles, Cal.

SOLICITORS WANTED.

The Cultivator wants two subscription solicitors, to put in whole time in the field. Salary or commission. Must have a bicycle. If you write us, state age, previous experience, if any, references and how soon you will be ready to work. We would prefer to have applicants call at our Los Angeles office, 203 New High st.

Stop Landlordism.—The Cultivator called attention recently, editorially, to the vast landed estates held by half a dozen men in California. The untold damage to our State by reason of such holdings was pointed out. Now comes the information that a syndicate has been formed in England, by titled aristocrats, to take up immense tracts of land in several States of the Union and introduce the system of landlordism as it exists in Europe, in America.

In a well known eastern journal appears the following item on this subject, which is sufficiently startling to warrant serious reflection:

"Foreign landlordism is reaching out its tentacles in the direction of America. A syndicate headed by the Earl of Verulem and the Earl of Lankerville owns a vast tract of land in Wisconsin. Alexander Grant of London county owns 50,000 acres in Arkansas. Mr. Elfenhauser, of Halifax, has 600,000 acres in West Virginia. A Scotch concern, Syndicate No. 1, bought 50,000 acres in Florida. The Holland Syndicate owns 5,000,000 acres of grazing lands in the West, and the German syndicate 2,000,000. It is said that 20,000,000 acres of good American land are owned by foreign landlords (English and Scotch). That is an area larger than the State of South Carolina."

When we recall the fact that 50,000 American farmers went over into Canada last year, leaving their farms in hundreds of cases, to be tenanted by foreigners, with no experience in our methods of agriculture, and when we recall the farther fact that farmers are pouring into towns from the country, increasing the city population and decreasing the agricultural products in a corresponding degree, we may well ask ourselves the question, when will this condition of affairs cease. We must have intelligent farming to accomplish results, and we can not hope for this under a system of landlordism, such as is in vogue in the countries of the old world, where unintelligent labor is wholly employed.

The Federal Government may be called upon to pass a law which will obtain in all States of the Union, as it does now in irrigated districts, over which the government exercises supervision, that no individual can take up more than 160 acres of land. This will be the saving to America of its lands, for its own people, and put an end to the graft of the foreigner whose eyes are turned upon our verdant fields with the purpose of acquiring vast domains. We want not great estates, but small farms thoroughly tilled, as are the lands in Japan today. We want not aristocrats for farmers, but toiling men and women, intelligent, educated and ambitious to make every acre they possess return its ounce of gold for the labor bestowed upon it.

* * *

Sharp Resolutions on the Agricultural Farm Project.—The Live Stock Breeders, at their annual session, last week, at Sacramento, passed the following resolutions in opposition to the project of locating the agricultural farm and school at the seat of the State University at Berkeley. They are worthy of careful perusal:

Wheras, The Legislature at its latest session enacted a statute providing for the purchase of a university farm and the establishment of a school of agriculture thereon; and

Whereas, There has been considerable but unavoidable delay in the selection of said farm, with the consequent delay of the opening of said school, the commencement of experimental work and the conduct of short courses of instruction in agricultural practice; and

Wheras, It has been advised by certain unauthorized persons that many of the most important provisions of the bill be ignored or departed from; and

Whereas, This bill was a farmers' measure, originated by them, drawn and advocated by them, and passed in their interests; therefore be it

Resolved, That we demand the enforcement of the bill as it was passed and according to its strict terms; and be it further

Resolved, That we earnestly request of the members of the commission for the selection of the farm that they proceed with all possible haste to select the said farm of the kind and in the locality provided for in the said bill; and be it further

Resolved, That we most earnestly oppose the suggestion that the farm be purchased in the vicinity of Berkeley or adjoining the University, because such selection would be in violation of the bill, and because suitable soil and climate cannot be had there, nor is the same susceptible of irrigation; and be it further

Resolved, That we deny that the sole purpose of agricultural education is to prepare teachers, specialists and leaders of thought. This is only one of its purposes, and modern experience has shown that to be effective, it must be supplemented by that type of practical and popular instruction which meets the demands of the great body of our farming people. We make no assault upon our College of Agriculture. Let it continue to prepare after its chosen method the very few young men which it is able to attract, leaving us free to educate our remaining youth to such extent as their means afford, and in the manner suited to their needs; and be it further

Resolved, That as this is a farmers' bill, we demand that we be left free to realize all of its possible benefits. We submit that we are the best judges of what we want, and as the farmer and producer pays all the taxes, including such as support all the departments of the State University, we feel that we should be permtitted to use some of our own money for the education of our own youth; and be it further

Resolved, That we favor the school of agriculture provided for in our bill, and ask that it be immediately organized.

There are thousands of our young men and women who need it and will immediately attend it for such length of time as their means and time afford, who are and will be unable to take a college course.

We hold in indifference the claim that such youth at the end of their periods of attendance are not thoroughly educated. They will be better educated than when they entered and by whatever name their condition may properly be called, they have been assisted, enabled to earn better livings, and to lead happier lives, and the State has been strengthened by having been given more enlightened citizens, who, as farmers, will create her wealth, rather than having been driven into other walks to, in too many instances, become charges upon her bounty; and be it further

Resolved, That we favor that character of instruction which is qualified to reach the great body of our farm youth, which offers something to everyone, no matter what his time or means, and which includes within its scope practical as well as theoretical training, and which has the direct purpose and tendency to illustrate the best possibilities of an agricultural life, and to incline the student to the adoption of the profession of agriculture, and that we have confidence that our bill properly carried out will effect these ends.

* * *

More Senatorial Boodling.—The four Senators under conviction in this State for bribery, are not the only ones who went wrong last winter at Sacramento, if we are to believe the testimony of ex-Senator Bunker, who has recently made a confession implicating other members of the State Senate in the same crime for which he was arrested. The confession connects the names of several persons in high social and political life and has created a sensation second only to the original charges of corruption made against the four boodling Senators. While it is to be regretted the Legislature contained corruptionists, it is a happy circumstance that their crimes were found out and that their speedy arrest followed. It may serve as a warning to other members of the Legislature to deal honestly with the public, through fear of detection, if their own conscience will not deter them from dishonest methods.

Ordinarily the death bed confession of a criminal may be looked on with more or less suspicion, for unless it is supported by correlative evidence it lacks the element of belief, but in this case the witnesses are living and the accuser makes bold to declare his ability to prove his charges. So we many reasonably infer that Bunker is telling the truth and that the drag net of justice will shortly haul from under cover the other fellows who have thus far escaped.

The whole people of California most earnestly desire that the boodlers shall be punished. Let the work of investigation go on, "let no guilty man escape," and may the lesson taught be severe enough to deter other officials in State or County employ from the reprehensible crime of grafting.

The College Farm Question.—Evidently a mistake is being made by the University of California, if the sentiment eminating therefrom is correctly reported, in attempting to force the location of the college farm and school at Berkeley, the seat of the State University.

The farmers of California are getting into line against the aggressive policy of the professors of the University, in a manner which is exceedingly interesting. Last week the Cultivator reproduced the resolutions of the Viticulturists' Association of St. Helena, wherein strong ground was taken against the proposed location of the farm at the seat of the State University. This week we give, in another column, the resolutions passed by the Live Stock Breeders Association, in session at Sacramento.

These resolutions, like those from the St. Helena association, are pronounced against the effort of certain Berkeley professors to grab everything in sight for the State University.

The time has come, it would seem, when the farmers, in whose interest the farm and school was supposed to have been devised, should express themselves on the subject. They should do just what the St. Helena association and the Live Stock Breeders' Association have done, pass resolutions of disapproval and forward them to the members of the commission. If the project is one to advance the interests of the farmers, they, and not outside interests, should have the deciding voice as to where the proposition shall be located. Concensus of public opinion is to the effect, and we believe intelligently so, that the farm shall be located where it can do the most good to the greatest number of farmers. If it is a farmers' measure, the farmers should derive the benefit from its location. If it was intended to be a proposition to advance the interests of the State University, and the measure was put through with that secret understanding the scheme was wrong in its inception and is very little above the danger point of political dishonesty. At least it was not sincere. So many things are put through legislative bodies, under the guise of benefitting the farmers, that the public has come to look with suspicion upon almost every proposition which comes up bearing the stamp of proposed agricultural improvement, and if now, in the face of the protests against it, the farm and college are taken to Berkeley the whole project will be censured by the farmers from first to last.

The hills around Berkeley are not suitable to an agricultural farm—as proposed. Practical irrigation can not be taught. The climate is not best for agricultural experiments, such as are needed. The education by college professors, undisciplined in practical agriculture, but learned in languages, philosophy and mathematics, is not what an agricultural farm needs. Such a farm, such a school demands practical men. California has had too much theory already. Let it now have a change to practical education. As Judge Shields put it in his address before the Live Stock Breeders' Association on this subject:

"All the farmers ask is to be permitted to spend some of their own money in their own way. They want a separate and popular college, not aristocratic and exclusive. They will support the university, but demand the right to place their sons in a purely agricultural atmosphere in school. They want a school where boys can go such time as they can, and as their means afford, to learn practical things, and they do not want to be told that that is not educational."

The Cultivator is not making any fight on the University of California, nor upon its faculty. We are all vitally interested in the greatness of that school, we want it to grow, to extend its influence, to become the greatest educational factor on the Pacific Coast, but to be this it is not necessary to take under its wing a school which is foreign to its work and for the development of which it is not properly equipped. That is the question, pure and simple. The farmers understand it and they understand it aright.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

The hot weather last week is reported to have injured the grape crop to some extent about Etiwanda.

Already over 300 car loads of apples have been sold by Watsonville growers to a Denver fruit firm, at good prices.

The Armsby company proposes to increase their fruit packing house at Marysville to four times its present capacity.

Orange packers and shippers in the Porterville-Lindsay district are preparing to send out fruit unusually early this fall.

The first car of Tokay grapes from Folsom, shipped August 12th, brought $2.25 and $2.35 per quarter crate in the eastern markets.

The Mountain View Register states that the fruit exchange at that place has been buying prunes on a three and a half cent basis.

A new fruit packing house is to be built at Nordhoff, Ventura county, this fall, to be ready for handling the coming crop of oranges.

Orchardists about Placerville report a fair pear crop. Some of the growers got as high as $45 per ton, but some orchards were under contract for five years at $20 per ton.

It is reported that the Windsor winery in Sonoma county will pay in excess of $15 per ton in order to secure enough grapes to make up its shortage of about one hundred tons.

Walnut buyers are said to be in the field in Orange county offering to make contracts with the growers for their crop at twelve cents, but are finding very few sellers at that price.

Oranges about Whittier are coloring very fast and it is now thought that that section will send out the first car of Navel oranges from Southern California this year, the same as last year.

The harvesting of Bellefleur apples in the Pajaro valley has commenced. Several carloads have already gone forward. The demand from all over the country for these apples is good and the chances for good prices are fine.

The Kaweah Lemon Co., of Lemon Cove, shipped its first car of lemons last week. This company has quite a large acreage just coming into bearing and will ship several more cars this season.

The fruit growers near Woodland have petitioned the supervisors of Yolo county to appoint a commission for the purpose of eradicating the diseases which threaten horticulture and viticulture in that county.

The new Placer county winery at Roseville commenced crushing grapes last week. The wine cellar is said to be the largest in the State, covering a floor space 90 by 160 feet, and has a capacity of one and a half million gallons.

Some trouble was experienced by apple packers at Watsonville last week in securing cars to ship fruit. Cattle cars were used temporarily to tide over the shortage. Several orchardists in the valley have sold their crop for the season by the ton.

Under the direction of the Los Angeles County Horticultral Commissioners, the orchardists of East Whittier are making a concerted attempt at this time to eradicate the purple scale by fumigation. More fumigation outfits are required to make the move a success.

The Whittier News says that the area in vineyards near that place amounts to between fifteen and eighteen thousand acres. The crop this year is not up to the average in size nor is the price high, $10, f.o.b., but the industry, taken as a whole, means considerable to that section.

John Hanna, of Mirafiores, informs us that he last week refused 12 cents per pound for his nut crop, taking the run of the orchard, made by an independent buyer. Mr. Hanna's trees are laden with the best crop of nuts ever borne by them, and he entertains a notion that he will receive 13 cents for them, or better.—Anaheim Gazette.

At a meeting of the old raisin association, held at Fresno last week, it was voted by the Board of Directors to commence suit against every member of the old association, numbering about two thousand, that the courts may settle as to the liability of growers who received the advance of three cents per pound two years ago on their raisins, the crop afterward selling for less than the amount advanced.

At the annual meeting of the Azusa Covina-Glendora Fruit Exchange, held recently, the reports showed that while the association shipped forty-nine cars less than last year, yet the total receipts were about $100,000 in excess of the former season. While the returns were not all quite in, yet the total cash received for the year's fruit will be close to $650,000. The shipments, as made from different associations, are as follows: Azusa Assn., 257 cars oranges; Azusa Foot-hill Assn., 191 cars oranges; Glendora Assn., 543 cars oranges; Charter Oak Assn., 65 cars oranges; Irwindale Assn., 155 cars oranges; Azusa Foot-Hill Assn., 91 cars lemons; A. P. Griffith, 13 cars lemons, Total shipments for the year are: 1211 cars oranges; 104 cars lemons.

AGRICULTURE.

The State grange will meet at Napa, commencing Tuesday, October 3d.

The bean crop in San Luis Obispo county is reported as much larger than last year.

Wulff Bros. last week bought two hundred and fifty acres of asparagus land on the Lower Andrus island, near Isleton.

The Fullerton Vegetable Association is sending out a carload of sweet potatoes a day. Last week they shipped ten cars.

The Empire Asparagus Co. is to build a cannery and will plant four hundred acres of asparagus in the delta lands near Lodi.

Owing to the blight in the early part of the season, the potato crop about Bayside, Humboldt county, will not be as large as usual.

The new crop of mustard about Lompoc is reported of excellent quality. Some sales have already been made at $4.30 per hundred.

California will use about 6,000,000 bushels of Washington wheat this year. The Washington crop will amount to about 35,000,000 bushels.

Hop pickers are very short in some Oregon fields. At Independence 200 men arrived by special train the other day, when 800 were expected.

Hop growers of California are organizing to control the selling of their product. It is intended to complete the preliminary organization at Sacramento next Sunday.

The sugar mill at Chino is now slicing about seven hundred and fifty tons of beets daily. Three to four carloads are being shipped out each day, mostly to eastern points.

Chas. Volkerts, the potato farmer of Hueneme, Ventura county, this year raised from one and a quarter acres of land two hundred and thirty-one sacks of very fine potatoes.

Fred Kemp, who is ranching in the Flint Hills, near San Juan, recently got a return of $510.00 from two acres of land sown to onions. The yield was 300 sacks to the acre, which he sold at 85 cents per sack.—Watsonville Pajaronian.

Under direction of the Fresno Chamber of Commerce, parties are at work visiting the farmers to secure contracts with them for planting and caring for certain acreage of beets. It is proposed to start a new beet sugar factory in that vicinity next year.

The hop picking season in the Sacramento valley is about over. The yield was better than was expected, this being true of quality as well as quantity. Buyers are attempting to bear the price of new hops and growers are forming a combination for self-protection.

Fifty acres of land have already been secured for the purpose of raising asparagus near Holtville in the Imperial valley, and it is hoped that farmers in that vicinity will raise enough more to bring the acreage up to two hundred acres, in which event a cannery will be built.

The Pacific Coast Ginseng Co., of Sunnyvale, Santa Clara county, was recently incorporated for the culture of ginseng. The company has two acres partly planted, the ground being covered with lath houses, as the plants require protection from the direct rays of the sun. Mr. Anderson, the president of the company, says that he sold $2000 worth of seed and roots last spring.

Nearly one hundred men employed in the hop harvest of D. P. Durst, near Wheatland, went on a strike one day last week, demanding an increase of pay of twenty cents on the hundred pounds. They have been getting $1.05 and insisted on $1.25. Not getting their demand satisfied, they commenced a war on the Japs who were also helping pick and drove them from the field. Work of picking was suspended, causing considerable loss to the grower.

LIVE STOCK.

Twenty-one hundred and seventy-five head of hogs were shipped from Imperial valley to Los Angeles packers during July.

Messrs. Fred Parks, W. J. Perry and F. W. Johnson, of Marysville, have secured a tract of land of 400 acres at Chico, and will establish upon it a dairy farm.

The live stock show at the Portland exposition opens September 19th and will last eleven days. The prize list totals about $40,000 and with interest from the best cattle producing regions in the world promises to be an event of national importance in stock circles.

MISCELLANEOUS.

Financially the State Fair was an even break this year.

The Fay ranch near San Fernando, consisting of 900 acres, was sold last week for $57,000.

The Marysville cannery has closed for the season, after a very successful run of two months.

A race meet is to be held at Santa Maria immediately following the racing at Hanford in October.

The new winery of T. L. Orr in Green valley, Sonoma county, is to have a storage capacity of 200,000 gallons.

A new cement plant, to cost about $2,000,000, with a capacity of five thousand barrels per day, is to be built near Santa Cruz.

The salmon pack for the Pacific Coast this year is estimated at $14,000,000, which is about $2,000,000 more than that of last year.

The Mound Water Co., which is owned and controlled by the farmers of the Mound District, Ventura county, who have one of the finest pumping plants on the Coast, began work last week on the contruction of a 1,500,000 gallon reservoir.

The Napa and Lakeport Railroad Co. has been incorporated and expects to construct a standard guage road from Napa through Napa and Lake counties to Lakeport, the main line of the road being ninety miles. The capital stock is claimed to be $2,000,000.

Salt River, near Phoenix, owing to high water, broke last Thursday, letting the water out and flooding the valley, causing heavy damages to the growing crops, as well as making it very difficult for farmers to put the land in shape for fall planting.

The State game officials arrested parties at Eureka last week charged with wholesale illegal traffic in deer hides. The seizures of hides were more extensive than any made in recent years. The officials are determined to prosecute to a finish all those implicated in the traffic.

A meeting, largely attended by farmers and others interested, was held at San Diego last Friday and an organization was formed and resolutions passed to the effect that the irrigation systems now in operation and under construction were well calculated to serve the nucleus of a great system to be developed in the future by the government. The plan of the new association is to endeavor to bring all the irrigation interests in that district under one head and have it taken over by the government.

The Byron Jackson Machine works, of San Francisco, have a new advertisement in this issue. This is one of the oldest and safest firms making pumping machinery in the State. If you are thinking of buying a pump send to them for a catalogue and don't fail to mention the Cultivator.

C. H. SESSIONS, ASSOCIATE EDITOR

CALIFORNIA LIVE STOCK BREEDERS' ASSOCIATION.

The California Live Stock Breeders Association met in Sacramento last Thursday and listened to some interesting papers, transacted the usual business and elected its officers for the coming year. It has become the settled custom of this association to hold its annual meetings during the session of the State fairs, and they have proved remarkably profitable to those who have attended. The officers elected for the coming year are: C. D. Pierce, president; S. B. Wright, vice-president; James Whittaker, treasurer; Professor E. W. Major, secretary; Directors—General W. R. Shafter, Judge Peter J. Shields, E. W. Howard, F. L. Hodgkins, William Pierce, F. M. Pickering, Isaac Bird.

Amongst the most interesting features of the session were addresses by Judge Peter J. Shields, of Sacramento, Prof. E. J. Wickson of the State University, and Prof. J. A. Craig, Dean of the Texas Agricultural College.

The liveliest discussion of the entire session was due to a series of resolutions regarding the location of the State farm, provided for by the act passed at the last session of the legislature. That act provided for the means to purchase the farm and named a commission to secure the best possible location which should comprise typical California farming land, at least one-half of which is to be irrigable land. The cause of the resolutions and the discussion which came up in the session of the live stock breeders was the remark recently made by Prof. L. H. Bailey that ten acres is sufficient for such farm and that it might be located in the hills near the town of Berkeley. This was thought to be preposterous by the greater number of the speakers attending this convention and the feeling was freely expressed that it was an effort on the part of the University to force the farmers out of their rights in this hard fought battle and deprive them of all that they have been striving for so long, a typical farm school.

The resolutions, which may be seen upon the editorial page, are couched in no uncertain language, and the discussions which followed their introduction were, if anything, still stronger than the resolutions. Professor Wickson, who had read a most interesting article on extension of agricultural education, was present and he suggested that the resolutions should not go too fast and assume that the case is lost, and minimize the strength behind the law. The agricultural college at Berkeley is not out of harmony with the farmers, simply because some one has said the farm should be at Berkeley. If the law is carried out in its spirit the farm will go where it ought to. The resolutions discount the location commissioners to select the farm location, and that is weakness.

To that, Judge Carroll Cook replied that he did not think the resolutions discounted the commission. They simply express the opinion and wish of those interested in agricultural interests. They assume the commission will do as it should do, but declare that the commission should not follow the advice of outsiders. Public demand is that the farm be not located at or near Berkeley.

In referring to the position Professor Bailey had taken, Judge Shields remarked:

"The bill says the land shall be typical of the best in California and California conditions, yet Professor Bailey scorned and sneered at that idea. He regretted that the professor came to California to obstruct the only genuine awakening of agricultural educational interest the State has had.

The bill does not hamper the university. It leaves its work free as heretofore. It does not discourage or deny it. Professor Bailey has aroused among agriculturists a universal feeling of resentment."

After further and extended discussion, the resolutions were passed without a dissenting voice.

In speaking of the true agricultural school in a later talk, Professor Craig, of the Texas Agricultural College, said that the true agricultural school must be one of short courses for those who can, and longer for those who will; it must have a farm typical of the field in which the student is to work. If in California no such farm can be secured to represent all soil conditions, then there must be experiment stations to supplement the farm. Once more he declared that the practical agricultural school must be free from the university, and not require severe educational qualifications.

THE SO-CALLED SHEEP TICK.

The so-called sheep tick is not a tick at all; but a fly without wings. The real tick is a variety of spider, and has eight legs as all the spider family have. But the so-called sheep tick has six legs only, as all the flies have. And it belongs to that class of flies which, like the mosquito, lives on blood which they draw from animals on which they prey.

Just now, in the spring of the year, these ticks are leaving the ewes on which they have been living—buried deeply in the fleeces—and especially so as the ewes are shorn, and are changing their homes on to the lambs in whose closer fleeces they find safer quarters and less exposure. They suck a large quantity of blood; this having been estimated at ten times their own weight every day. In fact they are sucking blood while they sleep, having their proboscis—which is really a pump fastened to the unfortunate lamb down into its skin, and thus they work, awake or asleep, day or night, protected by the dense covering of wool against all efforts of the lamb or the sheep to dislodge them. Of course when the sheep are shorn, the ticks are exposed to sight, as well as to the efforts of the sheep to pick them off the skin, and by natural instinctive efforts to save themselves, they leave the ewes and go on the lambs, which are very soon covered by them. Then the young lambs, unable to withstand the loss of blood and the continuous worry, as well as pain inflicted on them, stop growing and fall off in condition, and indeed in many cases unless relieved from these enemies, they hide themselves in some corner and die, for want of blood. Of course, it is always a time to keep a watch on the lambs to relieve them from these tormentors, but is especially needed when the ewes are sheared and the ticks become exposed to the light, and so leave the ewes and crowd on to the lambs which are then literally bled to death, unless relieved from these persecutors.

This may be done by dipping the lambs in any good prepared dip. But this is to be done with care that the dip reaches every part of lamb's body. The close fleece should be opened and searched for ticks, and a thorough clearance be made of them, during the dipping. The work is so easy, if done properly, that it should never be omitted. And it will save many lambs, that otherwise may be lost, for want of the relief.

THIS SKIMMING MACHINE takes the cream from the milk quicker than wringers squeeze water from clothes. It gets **a quarter to a half more cream** than by setting, because it uses centrifugal force—a force thousands of times stronger, quicker, more effective than the force that makes cream rise in pans.

Sharples TUBULAR CREAM SEPARATORS

Skimming finished five minutes **after** milking, because boy of ten can run Tubular **during** milking. No skim milk to warm, because skim milk is fed still warm from cow. **Half less washing, labor and expense,** because only cream is put away. Catalog X-260 explains clearly.

Palm Glen Jerseys

Final Dispersal Sale of Island and American Bred, to Highest Bidder Before Oct. 5th, viz.:

Oxford's Golden King 68922, born Oct. 11th, 1904. Oxford-Fon aine-Blue Belle-Finance Golden Lad. Nine of his near kin averaged over $1000 each at last sale of Mr. Cooper. Price $250—not half his value. Rosalres Rosette 180622, born Nov. 4, 1903, due Nov. 10th. Golden Lad-Flying Fox. Price $275 and worth far more. Owls Golden Belle 177464, born March 11th, 1903, due December 8. An Owl-Golden Lad. Price $225, and well worth it. Golden Kings Eloise 168276, born July 10th, 1902. now fresh. An Oxford-Finance cow. Price $200, not near her value. St. Lamberts Lady Jane 177425, born March 19th, 1903, due November 28th. A large, handsome cow of great ability. Price $2 0. Sultanes Lady Fern 187897, 9 months old, choice. Price $100. Sultanes Golden Queen, heifer calf, $50. Melias Golden Fernald, bull calf, $50.

Most of above were bought at a long price for foundation stock for a new herd; and there are none better in breeding, udder, teats, dairy form and productiveness. All are large, rich milkers, not one testing less than 6%. They will be sold to the highest bidder before Oct. 5th, but no bid will be accepted if less than one-fourth the price for one, or if less than one-third the price for entire herd. Time can be had on part if needed. This discount means loss to me, but continued sickness in family and sale of Palm Glen Place, requires their sale at once. To be appreciated they must be seen, so do not write but come and see and test.

When writing advertisers mention Cultivator.

The fact is that it is so easy to save both lambs and ewes from all this class of skin parasites that it is a matter for surprise that the owners of flocks do not practically exterminate them, and save much money as well as humanely relieve the sheep and lambs from much discomfort, and indeed torture, from these pests by the easy means suggested.

Every flock should be dipped as soon as shorn, and the lambs should be included in the treatment. But the common half-work done is nothing more than a method of continuing the evil. There are many flocks in the hands of foresighted and humane owners which are completely free from all this class of external enemies of sheep. The cost is not nearly so much as the saving made in the mere produce of wool from the flock. But there is a large gain made in the better growth of the sheep and lambs, as well as in the product of wool. It is a great mistake to think that the sheep turn out quite as much wool at the annual shearing whether they are annoyed by these parasites or are free from them, or that the lambs will make the same growth in spite of them. The facts are, that every discomfort to which the flock is subjected takes so much from the sheep both as to the regular growth and yield of flesh, and wool, as well. And while these losses may not be thought worth considering as long as the sheep survive, and live through them, yet the pocket of the shepherd suffers every year from losses that it would be profitable and easy to avoid. It is not a question of mere humanity and comfort to the lambs and sheep, but it is a serious money matter, and this has been so shown by the figures of the profits of the owners of flocks duly cared for in this way, and the losses of other flocks which have been neglected. There is a very common proverb in use: "It pays to be good." And there is no other way in which it pays so well as it does to be good as in respect of the shepherd and his sheep will repay every dollar spent on them in this way of securing ease and comfort, three times over—once in their growth, once again in their health, and the absence of occasional dead sheep, and again in the better condition of their lambs. And besides, there is that personal reward in the contented and satisfied mind of the shepherd who loves to see his ewes feeding in comfort, and the lambs play in pure overflowing happiness. And all this is gained at the mere cost of a little care and watchfulness which cost nothing, and a little work by which the expense of it is returned several times over.—Blooded Stock.

BATHING HORSES IN SUMMER.

Where a lake or river with a sandy bottom is handy, it is an excellent practice to give horses an occasional bath in summer. It is the quickest and most thorough way of cleaning a horse perfectly. Of course a good brushing daily will do wonders for a horse to keep him in best condition., but in very warm weather, when the horse sweats freely and the perspiration dries on him, no amount of currying and brushing will compare to a good bathing.

This will not only be refreshing and add comfort, but it will open up the pores of the skin, being a direct aid to the health of the animal to say nothing of the pleasure it gives a person to have a bright and clean horse to drive. If no lake or river is within easy reach, use a couple of pails of water with soap and a good brush. Then with a little patience and work a very good job can be accomplished.

* * *

The above from an eastern exchange is good, for the writer has followed the plan of washing horses in warm weather. The horses will stand under the hose and let the water run over their backs in complete enjoyment, apparently. Besides, if it is a warm day and they are allowed to stand in the sun to dry off after washing, it is most beneficial.

PORTABLE FENCE.

An enquirer in the Cultivator recently wished information as to construction of portable fence for keeping hogs. The following from an eastern exchange has a hint in that line:

Many people take the time to look into the advisability of making investments in a far-distant-sure-to-get-rich company, but who take no time, nor even consider the advisability of making investments in improvements at home. In many sections of the country stock raisers have taken to pasturing off standing corn with hogs and sheep. Reports from time to time have shown that while the business may seem a wasteful one, actual tests have proven the contrary.

To pasture off corn requires a great deal of permanent fencing or at least a moderate amount of permanent fencing or a considerable amount of portable fencing alone. Woven wire is by all means the best and cheapest fencing for this purpose. Ordinarily the 26 to 30-inch ribbon of woven wire will turn sheep and hogs. Especially is this true where the areas enclosed are large or larger than that to which the hog is accustomed. Woven wire fencing is very easily put up, and where only an occasional staple is used to hold it, such a securer will be found sufficient. Furthermore, fastened in this way, the fence can easily be taken down previous to moving it.

The main secret in putting up these portable fences is that of deeply setting, bracing and properly anchoring all corner posts. This done, the wire can be stretched tightly and made to remain so. Sagging here or being sprung there is unusual. Animals will not try it much and even though they do when but few intermediate posts are used, not much impression will be made.

In moving this fence the ribbon is either rolled up or pulled about loose with the aid of a team. The latter of course is the common method on the cultivated fields because here it is practicable and possible. Often after the wire is in place, a steady team hitched to a wagon is employed in stretching the wire instead of a wire stretcher.

In handling this sort of wire, the work can be hurried along because there is not much danger of wire cuts about the hands. For the most part one man can move a ribbon of wire much more easily than numerous single barb-wires and at least more quickly.

The value of these portable fences is scarcely known as it should be. Whether the area to be pastured be large or small, they are important. All farms have some kind of pasture that becomes lost unless early arrangements are made to save it. Some have corn, others have rape, and still others weeds. To be ready means that the fence must be gotten into place soon. 1000 rods may make $50 for you this year. You still have the fence left.

The best way to get rid of old sheep is to fatten them and sell to the butchers.

WANTED:

Dairy and Stock Men to know and realize what the following means. We will give you a three-year lease on from 40 to 160 acres in the Imperial Valley, Southern California, on a share basis. CARE OF THE BULL.

The bull is usually the unruly member of the herd, so that he must be confined to the stable, and few farms have a place where he can be at all comfortable. To leave him tied in a stall, on a hard floor, injures the feet; while a dirt floor becomes filthy. Then, too, the lack of exercise is an evil for which the owner sometimes has to pay dearly. It has before been stated that on our farm the bull finds an outlet for his surplus energy in pumping water. But that will not relieve him from standing on a wood or stone floor. To obviate that to some extent, this plan is followed: A long rope is let out from the side of the barn. A ring is fastened to lower end of rope, with which the chain he is usually fastened by is connected. He is allowed to stay in that place until the sun gets around, when he is put in the stable. In this way his feet come in contact with the cool earth for a number of hours each day, and if other exercise were not supplied a fair amount would be gained by the walking around which the long rope permits. An improvement on this plan would be a similar rope on east or north side of barn to which he might be removed afternoons.—Farm, Stock and Home.

THE COMPARATIVE VALUE OF ALFALFA.

Such is the composition of our minds that we need often to have a thing repeated, and dinned into us before we have absorbed it sufficiently to make any use of it. Take this plant, alfalfa. Thousands of farmers are taking up the cultivation of this most valuable forage plant. Yet a large proportion do not seem to have an adequate sense of its value and the importance of great care in curing it. Careless, shiftless methods are used, and the hay that is finally gathered in, is wretched stuff in many instances. All this because the farmer does not carry in his mind the right idea of its value and what he must do to save that value. We have often heard farmers say, "O, I can't afford to take the pains you do with it, etc."

When we ask them if they had that number of tons of bran lying out would they talk that way. They frankly say "No." Now whether alfalfa in its best estate is as valuable as brain or not, it is near enough to it, to justify the farmer having a better idea of its value than he generally does. If it were bran he would take care of it no matter what it cost. He would not stop a minute to count the cost of hay crops. The fact is these men have had no chance to note the difference there is in the feeding value of alfalfa cured in the cock under hay caps and that cured as they want to do it.

Secretary Coburn, of Kansas, gives a good formula for estimating the value of alfalfa as compared with other hay plants.

We repeat it so it shall not escape the mind and judgment of our readers. Here it is:

One acre of alfalfa yields as much protein as three acres of clover, nine acres of timothy and twelve acres of brome grass.

Let every farmer remember, who has any alfalfa to handle that he needs to take three times as much care of it as he would of timothy, and twelve times as much as he would of brome grass.

In the light of that comparison can any man be justified in saying he can't afford hay caps? or, he can't afford the extra labor of putting it into cocks?

We must measure some things by other things in order to get the right idea of things in our mind.

* * *

The above from Hoards' Dairyman shows the esteem in which alfalfa is held in the East and the care which it is deemed worth. From it Californians may get a lesson and give greater care in its curing here. The caps may not be necessary, but the allowing of such a valuable crop to lie and bleach for days, as we have seen it done, is certainly most objectionable.

THE STATE FAIR.

(Continued from First Page.)

kins, Cal., was on hand with a fine showing of Jerseys, Southdown Sheep, Berkshire hogs, and probably had a lot of Plymouth Rocks down at the Pavilion. Premiums—of course, and all along the line.

On Jersey cattle—six first, one second and one third, and four gold medals. On hogs—four first, two second, and two thirds. On sheep—six first, four seconds and one third.

Gen. W. R. Shafter and P. B. C. Sielcken were in the Jersey line and mighty fine stock they had.

L. V. McWhorter & Sons, of North Yakima, Wash., had no competition in Devons and while they took all the premiums it was at a loss in cash, as the premiums were cut in half on that account. From Washington, also, were shown some very fine Brown Swiss cattle—a comparatively new breed to this country.

Among the Berkshire breeders, Judge Carrol Cook and C. W. Reed made good exhibits.

The San Gabriel Valley herd of Poland Chinas, shown by W. R. McCaslin & Son, of Walsh Station, Sacramento county, also deserve special notice. Mr. McCaslin has two gold and two silver medals along with twenty-three ribbons.

The judging of the live stock was interesting. This year the stock was judged by Professor Major of the University of California, assisted in the matter of beef by Professor John A. Craig, Dean of the Texas Agricultural College, and Professor Leroy Anderson, of the State University, who assisted in judging dairy cattle.

The stock parade on Thursday was very fine, the procession being headed by the directors in carriages. First came the prize-winning Percherons, Belgians, Clydesdales, English, French and German coach horses, thoroughbreds, standard trotters, road and saddle horses, roadsters, carriage teams and Shetland ponies.

Next in order come the cattle; the Pierce Land & Stock Co. from Riverside Ranch, Stockton, with thirty-five head. Twelve Shorthorns from the Quinto Herd. Four second prizes were awarded this herd. Twelve head of Greenwood Shorthorns shown by J. H. Glide & Sons of Sacramento. These animals won all the sweepstakes but one. The Chowchilla herd of Shorthorns from Merced numbered twenty-five and were awarded five first and four third premiums. Gen. Shafter had eight head, four receiving first prizes and four second prizes. B. F. Rush and William Pierce, of Suisun, had ten head of Shorthorns in the line. Thomas Waite, of Perkins, had eight head of Jerseys, while seven breed were represented in La Palita Del Monte herd of Jerseys from Calistoga. The Brighton herd of Shorthorns, seven head of butter test cattle, were exhibited by P. H. Murphy, of Perkins. H. P. Eakle, Jr., of Woodland, led a yearling Shorthorn bull which received first prize.

L. V. McWhorter & Sons had fourteen North Devons in line on which they had taken eleven first premiums and the fifteen head of Brown Swiss cattle owned by J. M. Jayne received thirteen premiums.

During the week the weather was unusually pleasant and while a little warm and dusty at times, no fault can be found with the weather clerk. Taking everything into consideration the management may be congratulated upon a successful fair.

Sheep have excellent digestion and hence they utilize feed to the fullest degree.

DRY FEEDING.

(4th chapter.)

Dr. N. W. Sanborn, of Bellingham, Mass., writes in the Poultry Keeper a most interesting article on the "hopper method of feeding hens and chicks." Extracts from his article will finish our chapters on dry feeding and I hope may prove useful to many of us. He says: I have had more letters lately about the dry feeding method than in regard to any other two poultry matters. There is a feeling among poultrymen that the giving of mashes did not work as perfectly as it should. In the feeding of young chicks many who have used both methods think they see much gain in the use of dry feeds. A few of the owners of large plants who have adopted the hopper method say that it has reduced the cost of chicks and eggs.

More than one owner of several hundred hens says that the hopper way of feeding has helped him in the use of cheap workmen. It takes a good poultryman to feed mashes and meals of whole grain in the old way and not injure his birds. These men soon get into business for themselves and the proprietor of a plant of any size must take second-class help. This new dry feed method comes in to help make possible the running of poultry yards with indifferent help. It also makes easy the keeping of a few hens where the owner must be away during daylight hours.

* * *

Fitting Method to Conditions.—There is no method that is perfect. Every one has some disadvantage about it. The one that will best suit you and me is that one that most closely fits the conditions under which we keep hens and chicks. I am sure most of us can adopt to advantage more or less of the hopper methods.

It is fifteen years (longer than most experiments to prove anything in chicken feeding.—Ed.) since I introduced my hoppers of bran and grit, but took twelve years of experience before I dared risk my winter egg record on hopper methods. There is some loss of finely ground grain and meat in the hopper way of feeding, but it is too little to be hurtful to the pocketbook, and may be largely overcome by the careful construction of the hoppers.

The hopper method as applied to growing chicks is well worth trying. It does not do away with green food or free range. In fact, the hopper method, as applied to growing chicks, calls for grass range. It may not be free range, but it should be yards large enough to keep in green condition through the growing season.

* * *

What to Give for Food.—The newly hatched chick does well on some of the advertised chick foods. I take the chick food as I buy it in one hundred pound bags and add thirty pounds rolled oats and twenty pounds of wheat screenings. I feed the chick food, as I buy it until the chicks are twelve days old, and at that age add the wheat and rolled oats. I seldom feed meat scraps to my chicks until they are a week old, and often it is two weeks before they get animal food. The prepared chick food should be continued until the chicks are deserted by the mother hen, or cease to need the heat of the brooder.

* * *

The growing Youngsters.—When the chicks get their first coat of feathers and begin to range out into the fields, you can feed somewhat cheaper. The very best of results can be obtained on just two articles of food, cracked corn and beef scraps. This has been the diet of more hopper fed chicks than all others. They make rapid growth, are contented and in good condition to kill at any time. I know one grower of thousands of chicks, who uses wheat screenings and meat scraps for the feeding of the "youngsters" and he has the best of success. Of course he has to fatten any chicks that are to be marketed.

Chicks will not show much fat without feeding something of the corn nature. For growth you can find nothing better than meat and screenings, combined with good grass range. Screenings are hard to buy in the East, and most of us have to use cracked corn. Chicks handled in this way are more healthy and sturdy through the growing season than under the old ways of feeding.

* * *

Summer Feeding of Laying Hens.—When we come to the summer feeding of laying hens we find that the hopper method must be applied more thoughtfully than when we feed chicks. Hens cannot be fed as we feed chicks. Even hens on grass range put on too much fat if allowed access to corn in any form. If the hoppers are to be kept filled you had better limit your hens to meat scraps and wheat or wheat screenings. Even then a feed twice a week of barley will be helpful to the birds. This can be put into the hoppers when nearly empty of wheat and filled up with the wheat. If you can build hoppers that will not waste ground grain you can use this to advantage.

* * *

Summer and Winter Rations.—During the winter I use for ground grain a bin that is just a lard pail. This is nailed to the side of the pen and filled one-third high with finely ground grain. The birds waste hardly any when fed in this pail. This dry feed is made as follows: bran, two parts; corn meal, two parts; meatmeal one part; finely ground clover hay two parts. This is before birds at all times, and whole grain is fed in litter. In summer this needs to be changed in proportions.

A summer ration for laying hens that gives good results is made as follows: Bran, three parts; middlings, one part; cornmeal, one part; meat meal, one part. This dry feed before the birds at all times, with a light feed of wheat at night, will give a fine summer record along egg lines and will keep the birds in good condition to be moulted early in the fall. It does not do to feed males on the hopper method

A Profitable Poultry Ranch

FOR SALE

H. H. Holland, Fresno, Cal , offers the El Oro Poultry Farm, of about five acres, one mile from city limits and one-half mile from electric car line. About 400 mature fowls and 500 young ones, from best strains of birds. A home, a good living, and a margin of $500 to $1500 per year. One-third cash down, balance long time.

Place has growing alfalfa in every yard and several hundred fruit and shade trees. Entire place enclosed in 8-foot wire fence and divided into about 20 yards. I have 4000-gallon water tank, 6-horse-power gas engine, 2 100-foot wells, 4-inch centrifugal pump, brooder house, 2 large brooders, 2 large incubators, incubator cellar, water piped to every yard, 2-story barn, buggy sheds and outbuildings, garden tools, windmill and pump, 8-room house, acetyline gas plant, solar heater.

My reason for selling is want of sufficient time to devote to the business. Address

BUYS THE WORLD'S FAMOUS EGG FOOD NO. 4

MIDLAND

IF YOU WANT EGGS
YOU WILL FEED NO OTHER

Used by all the largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Hap-hazard feeding is no longer profitable. Try Midland Food and be convinced.

PETALUMA INCUBATORS
—AND—
BROODERS

The acknowledged standards of perfection. All poultrymen who have used these machines have supreme confidence in their ability to hatch and brood. Hence their ever increasing popularity. Winners of the GOLD MEDAL at the St. Louis World's Fair for greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1604.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A Filcher, Commissioner.

Sumptuously illustrated catalogue free; write for one at once. Send for our poultry supply catalogue No. 47, describing our line of supplies. Everything for the Poultrymen.

unless on grass range. Too many male birds are kept in small yards through the summer and fall and if fed from hoppers in small yards will overeat.

The hopper method has come to stay. It makes more easy work of poultry-keeping. It saves much sickness from overfeeding under the old ways. The death rate is reduced among growing chicks. Try it on a selected pen or two and I am sure you will be pleased with the results.

EDITOR'S QUESTION BOX.

Limberneck.—(N. M. S.) Pardon me for taking the liberty of writing to you in regard to a disease that is taking off my hens and young pullets. I have lost only one young rooster, seven young pullets and six laying hens. They began to get sick right after that hot weather we had last week; they begin to look droopy, and in just a little while drop down and cannot walk, their heads drop, their necks are perfectly limp and the birds lie in a kind of stupor, only once in a while they throw themselves around and struggle terribly just before they die. They are usually sick from twelve to twenty-four hours. They cannot swallow and the mouth has a thick slime in it. I have not saved one that has been taken with this sickness. I have been raising poultry on a small scale for over five years and never had a disease among them before this, only once in a while a case of roup. They do not have diarrhoea. I have been feeding a little heavier than usual for three weeks. I wanted to fatten some young roosters; got a sack of cracked corn and every one is fat and heavy. The hens were laying; three laid after they were taken sick. Now if you can tell me what caused the sickness and what to do for it I shall be thankful.

Answer.—Your hens had "limber-neck," brought on by the hot weather, and they were more susceptible to it from their being fat, and also from your feeding more corn than usual; corn is heating as well as fattening and that, with the very hot weather, caused the trouble. Your letter gives a most accurate and intelligent description of the illness, which is like sun stroke, or heat prostration in the human family. The first thing to do is bathe the head with cold or ice water, then I always give the hen one drop of tincture of aconite in a teaspoon of water. Dr. Sanborn says a remedy that has been successfully used is: Hyposulphite of soda; dissolve one teaspoonful in half a cup of water and give a teaspoonful of the mixture to each affected fowl every two or three hours. A teaspoonful of hyposulphite in a quart of water for the whole flock is a good remedy.

The following is said never to fail: Give the affected bird a piece of assafoetida about the size of a green pea. Use the gum form. Repeat the dose the second day, and the trouble gradually disappears.

In addition to this I would give more green food and less corn, and for about a week give the whole flock some Epsom salts, about a tablespoonful in half a gallon of their drinking water, and try to give them shade.

* * *

Various Questions.—(A. M.) 1. Will White Wyandotte chickens hatched February 12 last, moult this fall.

2. Will cocoanut cake, 25 to 35 per cent in the mash once a day cause them to moult—other ingredients of mash are bran, middlings, ground barley, Darling's beef scraps and alfalfa?

3. Some of these pullets—White Wyandottes—commenced to lay at 5 months. How soon can I use them as breeders?

4. How soon can I use the cockerels—February hatched—mated with the old hens?

5. Is it true, as some people think, that there is a larger percentage of infertile eggs from the White Wyandotte than from other breeds? If this exists, can it be overcome?

6. Some of my cockerels, otherwise pure white, have their plumage stained from the barnyard and from nest droppings. How can this stain be removed?

Answer.—They will have a partial moult.

2. It is not the food that causes them to moult, it is the feathers being ripe, like ripe fruit. Some foods help the feathers to ripen; cocoanut cake is one of these; so also is cotton seed meal and linseed meal or oil cake; these have to be cautiously fed or they will upset the digestion and cause liver complaint.

3. Eggs will hatch from pullets, but the strongest, largest, most vigorous young come from hens a year or two old. If a pullet is large and well developed and lays a large egg, you can commence to hatch when she is nine months old.

4. Cockerels can be used at nine months if they are large, vigorous birds.

5. This is an undecided question. Most old breeders think that the small combs and wattles of the Wyandotte males indicate a smallness or inferiority in the organs of reproduction; it is certainly true that the lively Mediterranean fowls are more productive than the smaller comb Americans. The only way of overcoming this is to keep the male birds vigorous and only allow them a limited number of mates (not over eight).

6. Washing with Ivory soap or pulling out the stained feathers two months before the show is the only way of removing the stain.

* * *

Heat Prostration.—(M. D. G.) I wish to thank you many times for the remedy for my turkey ailments in your most valuable paper of August 18. Your explanation was right, for we have had Indian Runner ducks on the turkey range and often water ran from the water trough down in the pond where they used to bathe, and the turkeys went there and drank at times. Your remedy proved a perfect success, not another turkey died after we commenced giving the pills, although it took several doses for some of them, they were so bad. Now, may I ask another question? Can you tell me the trouble when nice, healthy looking hens become weak and trembly in their legs, sometimes get so they can't walk at all, but flutter around and eat and drink as though nothing was the matter; both myself and neighbors have

same trouble; the hens have free run.

Answer.—Your hens are feeling the heat; they may be over fat, or not have shade enough; see my answer to N. M. S., and follow those directions.

* * *

Sick Chickens.—(J. L.) I have some chickens two months and some five weeks old, which seem to have the same trouble. They hardly grow, sit around hanging their wings, and I have lost quite a few already. Their droppings sometimes have a pale red color. The chicks five weeks old are still in the warm brooder, which we keep at 85-80 degrees, and the others are in sham brooders which have wire tops and lath floors.

Answer.—The symptoms you mention are usually due to lice and overheating.

The droppings being pale red indicate over-heating food and overheating at night in brooder, with a lack of cool fresh water and shade. The air slaked lime is very hard on chicks. I never use it in brooders. Dry road dust is much better, and is all the disinfectant a cleanly kept brooder requires. Be sure to sun your brooder every day, and once a day while this trouble lasts wash and scald them out with the kerosene and carbolic emulsion, for I very much fear that the trouble may develop into tuberculosis.

I would advise you to kill off the sick, move those that have not shown bad symptoms to fresh grounds and fresh brooder, give extra green food, clean water, and dust them with buhach for lice, and you may save some of them. The sick even if cured would never amount to anything. This may seem like heroic treatment, but I fear that tuberculosis may be the trouble. Sunshine is about the only cure and preventive of this disease, which if it once infects your brooders will sweep off your chicks year after year by the hundred.

* * *

Dry Feed.—(J. S., Gardena.) Please give Mr. Sampson's address, or some one who has adopted dry feeding method.

Answer.—Mrs. Basley tried for a year and gave full report of it in Cultivator of August 25.

* * *

Turkey Swell Head.—(C. E. W.): I too, come to the Cultivator for help. Indeed I hardly know how we would get along without it. Conditions are all so different from States farther east one feels at a loss sometimes.

I have excellent success with my chickens, having raised without sickness every one hatched. Now, one of my oldest seems to have rheumatism in his legs. They have always had dry, clean quarters. I have a few turkeys, one of them has a swelling on the lower part of its head, below the eye and on the under part of bill. The symptoms seem different from those described last week. He does not seem sick and eats well. The swelling became quite large and we opened it. It contained a clear, jelly-like substance. It seems to be filling up again. There are no sores in the mouth or throat, but a slight discharge at the nose on that side. I think another bird is showing slight symptoms of the same trouble.

Answer.—Your chicken has rheumatism. See answer to G. A. J. in last issue.

The turkey has swell-head. Give him a pill of quinine and assafoetida every other night for a week, and rub the head with carbolic salve, or with my roup cure—tablespoon castor oil, half tablespoon each of turpentine and kerosene, with 10 drops of carbolic acid and half a teaspoon of spirits of camphor. I keep this in a little sewing machine oil can always ready for use. It is an almost infallible cure for roup or catarrh in its first stage.

* * *

Various Questions.—(C. V. A., Subscriber). Will you kindly tell me through the columns of your valuable paper if two thoroughbred strains of chickens are crossed, will it prevent the eggs from hatching?

Also what is the cause of chickens picking and eating their feathers?

Which is the best season to hatch for profit?

Answer.—No, they will hatch, but I do not advise crossing breeds.

When chickens are idle, they (like human beings) find some mischief to do and learn all sorts of vices, feather pulling being one. Your chickens are probably too crowded. Try to find the ring leader and eat him. Give the others a great deal more meat for a time, or nail up some pieces of salt pork for them to peck and give them more green food and something to scratch for.

March or April.

FRUIT TREES FOR POULTRY RUNS.

One of the greatest mistakes that the beginner in poultry keeping can make is to prepare a range for his birds barren of all shade. Fowls delight and it is, in fact, their nature, to have access to woodland or underbrush, where they can dig around the roots and devour the countless worms thus found, at the same time escaping from the direct rays of the sun during the intense heat of summer. It would hardly pay to provide such shelter unless it were likely to yield some degree of profit in addition to benefiting the hens; certainly not on valuable lands. Hence the advisability of selecting proper varieties of fruit trees and planting them in the poultry runs. Fowls and the right kind of fruits do well together, one being capable of netting nearly as much money as the other, and every acre of poultry land not occupied by fruit trees is to a certain extent wasted or failing to produce all that it should. Provided the soil and location are suitable, pear, plum, cherry and apple trees may alike be planted in a poultry run. The point is to get good varieties of commercial fruit from reliable nurseries, and then set them far enough apart so that the trees will have room enough to grow and expand. If any dwarf varieties are selected, they, of course, should be placed much closer together. The proper distance apart for plum trees is twelve feet; for cherry and apple trees, twenty feet. When first planted the run should be sown in blue grass and clover, as these will add greatly to the fertility of the soil, and until the trees have become well established they should be surrounded by a fence of chicken wire. After that the fowls will do no harm to their roots—not even if the soil around and between the trees is stirred up and cultivated, as it should be, so that they can scratch and wallow in it. Indeed, poultry will in this way keep down insect pests, such as borers, grubs, caterpillars, worms and the like, by eating them up as fast as they appear; moreover, when the fruits have grown sufficiently, so that the rotten and wormy ones fall, they will take care of these, and the fruit as well as the worms is good for them. The trees, on the other hand, will afford the poultry an excellent shade during the heat of summer and, all in all, the two will thrive together in a marvelous manner. Keep the trees properly pruned, remove any worms that may in the beginning secure lodgment among their foliage, turn up the soil about their base occasionally and enrich it with a little manure every year, and poultry may be relied upon to give them about all the further attention that they will need.—Agricultural Epitomist.

If it be true, and the theory seems very plausible, that grit is valuable because of what it contains rather than as a food grinder, it behooves us to pay more attention to the kind of grit we provide for our flocks.

If you can't do just what you would like to do with your poultry, don't be discouraged. Do the best you can.

If charcoal be not a part of your regular ration provide it now, during the moulting season.

A Visit to the Large Packing Houses in the Eastern Cities

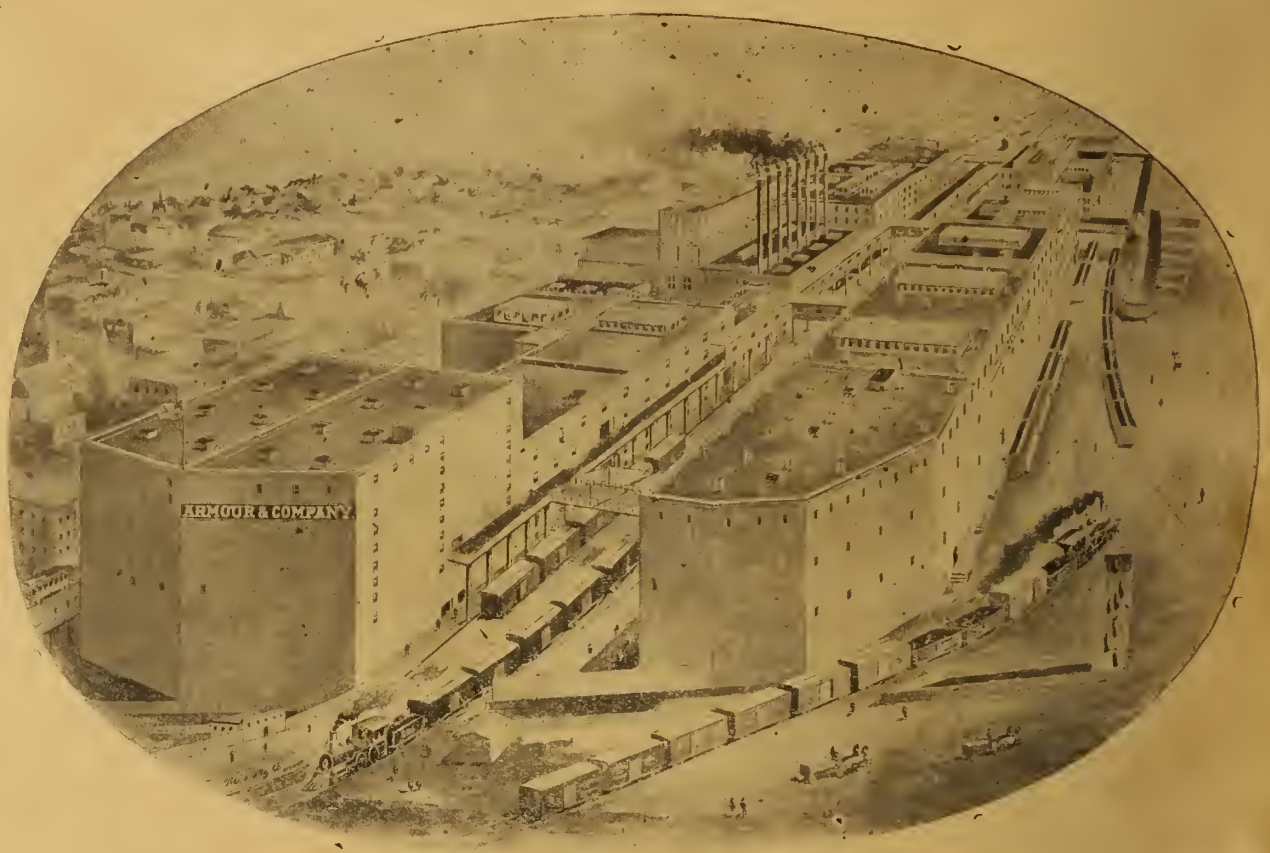
In Three Chapters.--Part I.

WILL HAVE BRANCH EAST.

Mr. A. R. Coulson, president of the Coulson Poultry and Stock Food Co., arrived home from the East on Saturday evening. Mr. Coulson had quite an extensive trip, stopping over a day or two at each of the following cities: Salt Lake City, Denver, Lincoln, Omaha, Kansas City, St. Louis, Chicago, St. Paul, Minneapolis, Spokane, Seattle, Tacoma, and also a week at the Portland Fair.

The Coulson Company is planning to establish another factory in Omaha, which will be a large institution. (From Petaluma Argus.)

Few people realize the magnitude of the packing house industry carried on in the east. Mr. Coulson's visit to the plants of the Armour Company and a few photographs taken of some of the principal parts, which we reproduce herewith, will give the reader some idea of the immense number of animals killed every day by the Armour Packing Company; and this is how they get so many hearts and livers to make the Heart and Liver Meal (animal meal) used in making Coulson's Special Dry Chick Food, Coulson's Egg Food, etc.



SHOWING PLANT OF ARMOUR PACKING CO. AT OMAHA, NEBRASKA.

Mr. Coulson first visited the Armour Packing Plant at Omaha (see illustration.) Here they have a number of immense buildings, each occupied for different purposes and in their office building there are several hundred clerks taking care of the books and correspondence, etc., and an army of some 4000 men employed about the plant.

HOGS COMING OUT OF SCALDING VAT AND SCRAPING MACHINE AND FIRST PROCESS OF DRESSING.

Mr. Capune, manager of the Animal Food Department, took the writer through the various departments, showing how the animals were killed, dressed, etc., all of which was very interesting. In one pile there was about 5000 hearts taken from the pigs and cattle that were killed that day, these hearts were cooked in a large steel tank that reached from the first floor to the fourth floor, and there were immense furnaces in the basement that heated up these tanks and cooked the meat therein. After the hearts were thoroughly cooked, then they were taken out and put into long boiler-like tanks, which had big revolving screws running through the center, and which kept stirring up the hearts until they were all crumbled up into a fine meal. These tanks were also heated up by furnaces underneath, so that the hearts were again thoroughly baked and dried. At the end of two hours the hearts were converted into a dark yellow meal, as dry as powder.

This Heart and Liver Meal is put in bags and every few days, or as soon as a carload is accumulated, it is shipped to the Coulson Poultry & Stock Food Co., at Petaluma, California, and is used in preparing **Coulson's Egg Food and Coulson's Special Dry Chick Feed.**

This Heart and Liver Meal is **great food to make chicks grow.** The Coulson Company uses lots of it in making Coulson's Egg Food, and Special Chick Food. There are many differ-

PROCESS OF KILLING AND SCALDING HOGS AT ARMOUR'S

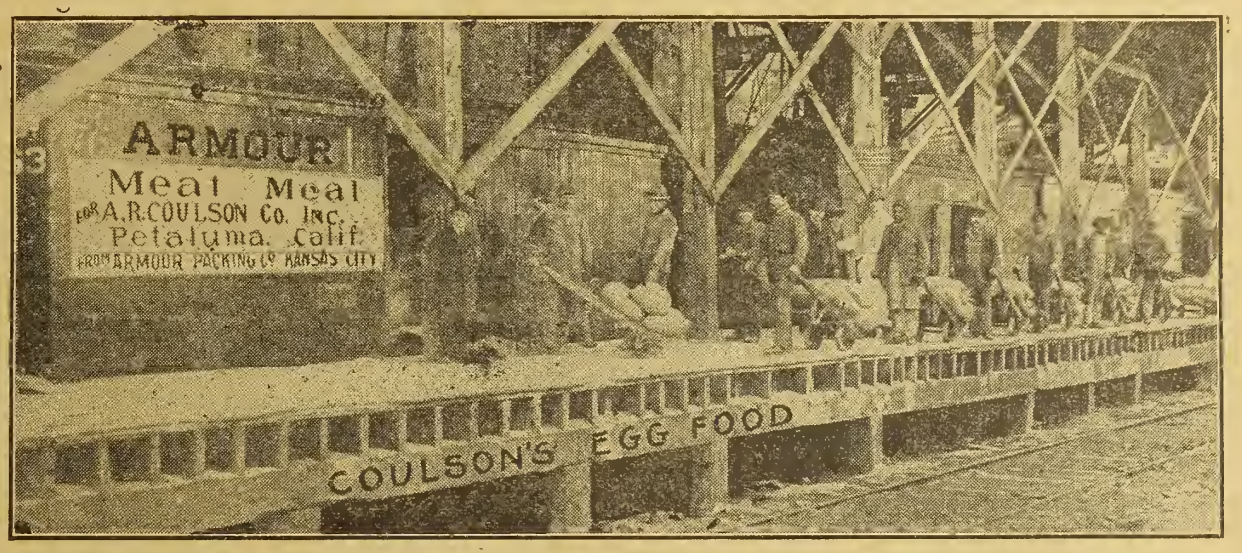
Process of cleaning and dressing hogs. Also U. S. Government inspection and view of the chill room at Armour's.

ent poultry foods on the market, but the Coulson Company is the only firm that goes to the expense of getting such good material and they have the exclusive contract with the Armour Packing Co. for the Hearts and Liver Meal. No other firm can get any of it; therefore no other Poultry Foods are like Coulson's.

If you want success with poultry, feed the pullets and hens **Coulson's Egg Food** and feed the baby chicks **Coulson's Special Dry Chick Feed.**

Ask your dealer for Coulson's. Send to us for free poultry account book.

In the next issue we will tell about the Kansas City plant.

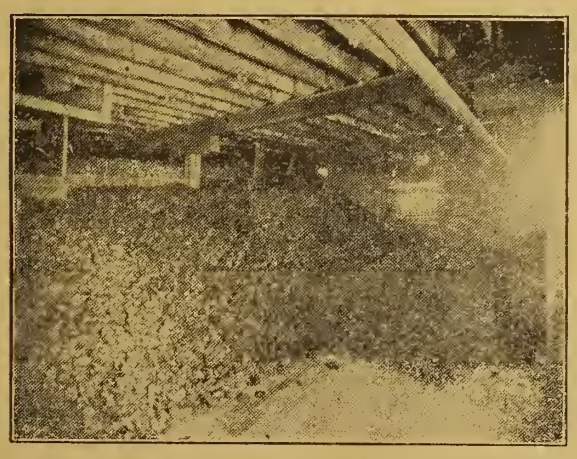


AT ARMOUR PACKING CO.

Loading cars of 400 sacks of Armour's Meat and Blood Meal for Coulson Co. The meat meal is made from hearts and liver, baked to a crisp and ground fine. The Coulson Co., Petaluma, Cal., has a contract to take the entire product of this meat meal and it is used in preparing Coulson's Poultry Foods. Ask your dealer for Coulson's Egg Food and Coulson's Special Dry Chick Feed.

Feed the Chickens Coulson's Feed

There's Nothing Better



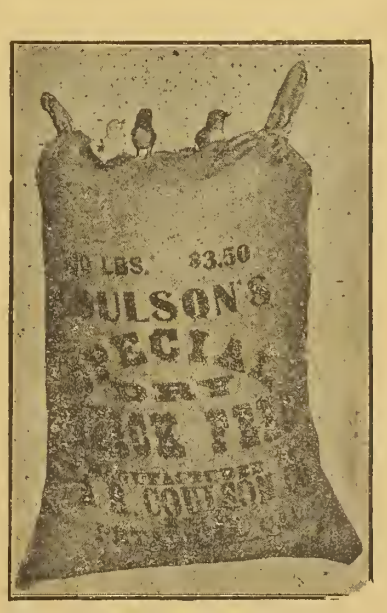
PHOTOGRAPH SHOWING

A HUNDRED THOUSAND BAKED AND DRIED HEARTS AND LIVERS

These are ground up into small pieces and used in mixing COULSON'S SPECIAL DRY CHICK FEED AND COULSON'S EGG FOOD.

A sack of Coulson's Egg Food.

A mixed feed for chickens to make the hens lay lots of eggs. This feed is composed of about three-fourths ground grains or mill feeds and nearly a quarter of animal meals, that is fresh, fine ground bone, dried blood and the heart and liver meal.



You will have the best success you ever had in raising chickens if you will feed COULSON'S SPECIAL DRY CHICK FEED. Send for sample. It's good for turkeys as well.

STRATEGEM.

He was an aged man,
Of ninety years or more,
And at the thought of dying he
Did wax exceeding sore.

And what did he, the aged man,
To wholly calm his fears?
He robbed a safe so they could give
Him ten or fifteen years!
—New Orleans Times-Democrat.

A Lost Count

Daisy was as pretty as a June cloud and as fickle as a March wind—the brightest, giddiest girl in our village, yet withal wise. with a strange feminine wisdom. Frolicsome, demure, gay, serious, full of irony, of sympathy, of raillery, of sentiment—she had moods as many as a humming bird's hues.

Thomas loved and courted her, and so did I, and so did every other young man who dared to hope in the least for her favor. And she was impartial, almost indiscriminate with her smiles. As time passed, however, her choice seemed narrowed, until it appeared that it was betwen Thomas and me. He was the more desirable match, being both gifted and well-to-do, but something made me hope, though not without misgivings, that she preferred me.

I determined to declare my heart and know my fate. Many times I sought opportunity to do so, but she avoided my avowal, and so cleverly that I could scarcely be sure she did it purposely. How long she would have forestalled me I cannot guess, but for a chance that drove me to desperation. Passing her home one bright, warm day in May, I saw Thomas with her among the flowers. They stood close together, and he was speaking rapidly. I thought intensely, while her eyes were downcast. As I drew near she saw me, and leaving him, ran towards the gate, calling me.

"Come in, Arthur, and see my flowers! My pansies are the finest you ever saw."

"Thank you, Daisy. Another time—I'm in a hurry this morning. Good morning, Thomas."

"Too bad you can't stop," she persisted. "Thomas and I are having a fine time."

Thomas didn't look as if he was. I passed on with burning heart, and when I last saw them he was standing with her at the gate, I decided then that I must not lose any further time. The very next morning I would make my attempt. Would she receive this as she had the avowal of Thomas?

The next morning found me with her in the garden with the flowers. The surroundings of bright blossoms and mellow spring sunshine and azure skies and lisping leaves was an ideal one for a declaration of love.

"Daisy," I said, " I have long wanted to tell you—"

"Oh, now, Arthur, don't; please don't—there's a good man! Why do yon men always get sentimental in a posy garden?"

"I must tell you, Daisy. I love you. You are to me what the sun is to the flowers. I cannot live without you."

I tried to take her hand, but she skipped away and stood on the opposite side of one of her loved pansy beds.

"What a grotesque illustration!" she cried. "A great, strapping six-footer likens himself to a little blossom and compares a small black gypsy of a girl to the g-r-e-a-t big blonde sun! How ridiculous!"

"But, Daisy," I argued, "whether the illustration is a good one or not, it's a fact that my heart and life are yours, and that I cannot live without you."

"And if I say no, you'll be telling some other girl the same thing in just a little while. Talk about girls and make believe!"

"But you know this is not make believe, Daisy. I knew what Thomas was saying when I passed yesterday."

"How discerning!"

"And as I thought of it yesterday I knew I could not live without you. I knew if you accepted him, I could never be happy another day if I should live for a hundred years."

"Yet, you call him your friend!"

"Yes, and a fine man. But I want you for myself."

"Thomas is most as silly as you are. He talked just the way you are talking now. Really, you are unoriginal. It seems a girl cannot be friendly witb you men without having to listen to such stupid talk."

"But it is true. How can we help loving you?"

"Oh, just be sensible. Just say, we'll have a nice time with Daisy, and not be foolish and sentimental, as I do about the boys," she added, archly.

I leaped the flower bed and stood beside her. She had not taken her eyes from my face, and I remembered that yesterday, when Thomas spoke with her, her long lashes concealed her eyes. But as she looked at me, while there was a sparkle of amusement in her dark orbs, there was earnestness, too, and though her words were inconsequential, at best, I did not despair.

The most beautiful picture in my memory is that of Daisy among the flowers as she stood that moment with her head high in mocking challenge.

"Seriously," she said, with a gravity I had never before heard in her voice, "I know I must decide some time. And it is such a great decision that—that one cannot make it too solemnly. So let me show you the sights." She tossed her head and stretched her hands toward the flower beds.

"Do you want time to decide? Don't you know your own heart? Don't you know whether you love me or not?"

She stopped as she was turning, and stood motionless for a moment. Then she said:

"You shall have your answer now, you persistent fellow."

She ran quickly to a bed of daisies, sat down upon the grass by them, plucked one, and holding it up to me, said:

"I've always been lucky with flowers. What luck do you suppose one will give me?"

And then, while I looked on, she plucked off, one by one, the rays of the flower, saying as she did so:

"Tom, Art, Tom, Art, Tom, Art, Tom," until there were but a few left. She counted so rapidly that I could not keep up, much less anticipate the result by counting the petals remaining. Suddenly she interrupted herself with a shrill little cry of: "Oh! there's my brown thrush!"

She leaped up and stood beside me pointing. I did not see him at first.

"There he is in that maple away up at the top." She spoke almost impatiently. "He's the lovely fellow that has been singing to his sweetheart these two months."

Then she resumed her counting:

"Tom, Art, Tom, Art, Tom, Art." She said "Art with the last petal, and then, "Oh, fiddle!"

"I won!" I cried eagerly.

"Yes," demurely.

"Is it yes, then?"

I seized her hand, and this time she did not seek to withdraw it." This is a public place, Art; don't be foolish," she said, as her long lashes drooped and a rosy glow suffused her cheeks.

Since our marriage I have confided to her that I knew I lost in the lottery. She said Tom twice in succession.

"Did I?" she asked, innocently. "How odd! It was the interruption of the thrush that made me do it—perhaps."

Asking Her

To the end of his days Ellithorpe will never forget the sensation when he read the simple, cold blooded announcement in the society column of the newspaper. The sickening feeling which overwhelmed him still lingers vividly in his memory.

The notice was to the effect that the engagement of Miss Rose Burlingame to Doyle Jenkins was announced. That was all, but it was the end of the world for Ellithorpe.

As he glared at the crumpled newspaper he admitted that he had dallied. For two years he had been a constant caller at the Burlingame home. For two years he had lived in the light of her presence and hadn't opened his mouth to tell her how he felt about it. He had always meant to do so, but he was shy. Never in his maddest dreams had he pictured any other girl wearing orange blossoms and a tulle veil for him. And now—

If it had been any other man than Jenkins! But he was honest enough to admit that he would have been just as enraged and upset no matter who had been his lucky rival. Still, it did him good to pretend his wrath was because Jenkins parted his hair offensively in the middle and had a tendency to lisp.

* * *

Ellithrope pusbed his dinner away without a look at the tempting chop and left the club. He wanted to walk and think it over. There was plenty to think about—what a fool he had been, for instance. He might have known others admired her as well as bimself. What a conceited chump he had been to fancy it didn't matter when he spoke! Why, there were always plenty of callers hovering about Rose, but he had been so wrapped up in his own liking for her he had not thought about anything else. Now he was well paid for it.

Where on earth could he spend joyful evenings now. For he could never sit in the same room with the successful Jenkins without strangling him, he was grimly certain. And Rose wouldn't care to have him call now that she had picked out Jenkins. Ellithrope groaned aloud.

Suddenly an overwhelming desire to see her again, to view her in the light of this stupendous change, came over him and he boarded a car. It was quite right he should call and offer his congratulations, he told himself miserably. All the way out there he was rehearsing different ways of doing this without giving her a hint of the anguish in his soul—for he had resolved never to let her know.

When he reached her street he had not decided whether to begin the convrsation in a calm and everyday manner, gradually leading up in an incidental way to the news of her engagement as though he merely remembered to speak of it along with other pleasant news, or whether in a sprightly and jesting manner, to plunge into the subject at once. He rather inclined toward the former as more likely to give Rose's vanity a letting down and to show her if she had any lingering suspicions as to his caring deeply for her that she was wholly mistaken.

The maid had ushered him into the

HELP!

Settle Your Own Country

The Santa Fe

is doing its share in trying to send more farmers to your country. You can help that work by a little effort.

Every reader of this notice is requested to send to the undersigned a list of his friends in the East who may possibly be interested. Literature regarding your country will be mailed to them, and any questions they ask will be fully answered.

1007 N. ALAMEDA, LOS ANGELES

When writing advertisers mention Cultivator.

Burlingame library, and at sight of the familiar room his heart dropped several more notches. Decidedly he would choose the first way; maybe he would even apparently forget to mention her engagement till he was ready to go home, just as though it had nearly sliped his memory.

"Good evening, Dick," she said just behind him.

Ellithrope sprang to his feet. She was looking perfectly natural, happy and placid, not at all important, as he had fancied she would, and she walked over to a chair as though nothing had happened.

Ellithorpe's eyes blurred and he realized to his horror that he couldn't follow out his program.

"I can't believe it, Rose," he heard himself saying, huskily.

"Believe what?" she asked in surprise, which grew as she noted his tragic attitude.

"This," said Ellithorpe dramatically, fishing out the newspaper folded at the fatal notice and handing it to her. As the girl scanned it her face turned crimson. There was a sparkle of wrath in her eyes.

"How perfectly horrible!" she cried, vehemently. "It's a mistake. I can't imagine who put it in. And Doyle Jenkins of all people! As though I—why, I never heard of such a thing!"

"You arn't engaged to him?" Ellithorpe shouted.

"I should say not!" said Rose decidedly.

It was then Ellithorpe found his wits and his voice.—Chicago News.

Cookery Recipes

Fig Preserves.—Gather the fruit when fully ripe, but not cracked open; place in a perforated tin bucket and dip for one moment into a deep kettle of hot and moderately strong lye (some prefer letting them lie an hour in lime-water and afterwards drain); make a syrup in proportion of one pound of sugar to one of fruit, and when the figs are well drained put them in the syrup and boil them until well cooked; removing, boil the syrup down until there is just enough to cover the fruit; put the fruit back in the syrup, let all boil, and seal while hot in glass or porcelain jars.

* * *

Canned Figs.—To three quarts of boiling water add two heaping teaspoons soda. Dip your figs in the water for one minute and skim them out; wash thoroughly in two or three waters, or until there is no color left in the water. To ten pounds of figs allow eight pounds of sugar; add just enough water to dissolve the sugar; when boiling hot, drop in the figs, having first selected them with care so as to avoid any that are broken or overripe; let them simmer slowly two hours; now remove the figs and boil down the syrup until quite thick; replace the figs; bring all to a boiling heat, after which they are ready for canning in the usual method. A few slices of lemon with its juice will improve the flavor.

* * *

White Fig Marmalade.—A delicious marmalade is made from white figs. Take perfectly ripe and fresh figs, peel off the thin, soft skin, and to every two pounds of figs use one and a half pounds of sugar and the grated peel of a large orange or lemon; cut up the figs and mash them with the sugar, adding the grated yellow rind and juice of the orange or lemon; boil all together until the whole is reduced to a thick, clear, smooth mass, stirring frequently from the bottom. When done, put into jars while hot and cover closely.

Those who like less sugar can use one-half pound sugar to a pound of fruit, and it will keep perfectly, provided it be boiled very clear and smooth.

* * *

Stuffed Figs.—Use "bag figs" (dried) which have not been pressed. Cut a small slit in the stem end of each fig and work in two or more blanched almonds.

Another mixture which is very palatable is a paste made from almonds, walnuts and hickory nuts, to which are added a few drops of sherry. A portion of the soft meat of the figs is first taken out, using a knife or a small pointed spoon. The fig is now filled with the paste. When filled, press the opening and roll in granulated sugar.

* * *

Fig Tart.—Select a dozen choice dried figs and stew them in enough water to cover them. Add two cloves, a small piece of preserved ginger, chopped fine. When tender, take out the figs and remove the spices. Add enough sugar to the water to make a good syrup and a couple of spoons of ginger syrup. Then boil for five minutes, and add a little hot water if it gets too thick. Next add a teaspoon of lemon juice. Return the figs to the syrup and set aside to cool. Put one or two figs and a spoon of the syrup in each tart before serving.

Whip one-half cup of rich cream until stiff, and sweeten slightly. Add one-half cup of dried figs, cut fine, preferably into minute dices, by aid of a sharp knife. Stir these very lightly into the cream and sugar a few at a time. Fill puff paste with the mixture and sprinkle with maple syrup or dust with cinnamon, according to taste.

* * *

Fig Marmalade.—Use only fully ripe figs. When they are considerably wilted they are cut. Cut in halves and scrape out the inside pulp; mash and strain through a very coarse sieve. Put into a glazed dish and place the latter in boiling water. Boil constantly for one-half hour and then preserve in sealed glass jars, like canned fruit. This marmalade is very fine; can be eaten with meat, or alone with cream. It is a fine relish if made from good, sweet figs.

* * *

Pickled Figs.—Seven pounds of figs picked just before shriveling, three pounds of white sugar, one quart of vinegar, one teaspoon of salt, one teaspoon of allspice, one teaspoon of ginger, one tablespoon of cloves, two tablespoons of cassia buds. Boil together for four hours, put spices in a thin bag to keep pickles clear, and more vinegar if too much evaporates, and add sugar when nearly ready. When the sugar is dissolved, add the figs. Simmer until tender.

To ten pounds of figs take four pounds of brown sugar, one quart strong vinegar, one large cup of whole spices of the following kinds: cloves, cinnamon, allspice and cassia buds. Boil vinegar, sugar and spices first, and when sugar is well dissolved add the figs and boil until tender. The figs should have been picked before being shriveled. Put all in jars; pour out the liquid three mornings and let come to a boil and return to the figs; then close the jars.

Spiced Figs.—Peel ripe white figs, and to ten pounds of the figs add five pounds of brown sugar, one quart of vinegar, one ounce of cinnamon, one-half ounce of allspice, one-half ounce cloves, the spices to be tied in bags and boiled with the sugar and vinegar. When the vinegar and spices have come to a boil add the figs, a few at a time, to prevent mashing, and boil until they look clear. When all are done put into jars and pour the vinegar over them hot.

* * *

Crystalized Figs.—The figs must be picked when fully ripe, but before they are shriveled. Take figs of as even size as possible in order to save assorting afterwards. Simmer in a kettle for twenty to thirty minutes, but do not allow to boil. When ready the figs will have become clear and transparent. Drain off the water. Prepare a strong syrup of best white sugar and drop the figs in. Keep this in a cool place. In from twenty-four hours to thirty-six hours the figs will have absorbed most of the sugar and the syrup become very weak. Draw off the syrup, add more white sugar, and thus make the syrup stronger. Simmer, but do not boil. Drop the figs in, and test again in twenty-four hours. If the syrup is weak renew the process. When the syrup retains its strength, the process is discontinued. Prepare a very strong syrup of best white sugar; simmer, do not boil. Previous to this the figs are dried in the sun or in drier, until they ring slightly when dropped on a stone floor. The figs should, however, not be so dry that they can not be readily indented when pressed between the fingers. Now immerse these dried figs for a few seconds in the strong, hot syrup, then drain off and place on wire trays in a hot-air drier or in the hot sun, if on a warm day. The syrup dries quickly and leaves the figs glaced. If crystalized figs are wanted, the figs are dried slowly in the shade, in which case the syrup cystalizes instead of producing a glace.

* * *

Candied Figs.—Are made only from young, green figs not yet fully ripe. Place in glass jars, pour on salt water and steam until soft. Pour off the salt water and pour over a syrup made of one cup of sugar to three of water. After a day take out, place on wire screens, and allow to drip for one or two days in a warm place. Place again in jars or earthenware; cover with a syrup made of one cup of sugar to one and one-half cups of water. After a day take out and allow to drip. The third soaking should be in a syrup made of one cup of sugar to one-half cup of water. In this syrup the figs are allowed to remain as long as possible, or until required. Take out, drip and roll in confectioner's sugar in a pan made lukewarm. When the figs have absorbed all the sugar they can they are taken out and packed in large boxes with powdered sugar. The preserved fruit is afterwards repacked in small boxes for the market.

HOMELY HINTS.

A burned saucepan should be filled with cold water to which a rather liberal allowance of soda has been added. Let stand for an hour or so, then heat the water slowly, and let simmer for a few minutes, and the burned particles will come off quite easily.

After making pies, there are frequently small scraps of pastry left. Roll it out in a thin sheet and spread with chopped dates, figs, raisins and nuts mixed. Lay another sheet of paste on top, then roll lightly. Cut with a heart-shaped cutter and bake delicately. Cut the pastry into rings and fingers, sprinkle with well seasoned, grated cheese and bake lightly. Cheese wafers of this sort make a very palatable salad accompaniment.

To take grease out of dress goods get from your druggist a piece of French chalk—with a penknife scrape off enough of fine dust to cover well the soiled spots, and lay the garment away carefully for some hours—a day or two, perhaps—then shake or brush it off gently. If the spots are not entirelyl removed repeat the process. I know of nothing more effective.

When frying fish, if a little salt be added to the fat the flavor of the fish will be greatly improved. Eggs are now so dear, and soon will be dearer, that instead of egging and breadcrumbing fish for frying, just dip the fish in milk and then seasoned breadcrumbs, and you will be glad of this wrinkle.

Try rubbing a mirror with a ball of soft paper slightly dampened with alcohol, then with a duster on which a little whiting has been sprinkled, and finally polish with clean paper or a wash-leather. This treatment will make the glass beautifully bright.

ABOUT ANTS

They are very persevering little creatures. *Say!* If you will use Kellogg's Ant Paste, following directions, and fail to rid your house in 24 hours, we stand ready to refund the price at any time Price 25c. If your druggist doesn't keep it, we will send it prepaid by express, 40c. Agents and dealers wanted.

ESCONDIDO IS FREE.

Escondido is now enjoying the unique distinction of being free from public debt. Last Saturday saw her irrigation bonds to the extent of $350,000 and interest go up in smoke. Needless to say, well deserved congratulations are pouring into the beautiful valley down in San Diego county.

Mutual ownership may or may not be preferred to public ownership, but one thing is certain, Escondido has the water and is owing no man a cent.

But what is better still, the water may be increased and increased. The present system consists of 13 miles of tunnels, flumes and canal, diverting the flood waters from the San Luis Rey river where it drops through a wildly picturesque gorge, to the beautiful Von Seggern valley, where it is impounded. Controlled at will there, the water drops 400 feet and enters the distributing systems of cement canals, steel tubes and open flumes, which also includes the smaller reservoirs and pipes of the city system. It constitutes an ideal proposition, an engineering triumph. But this is not all; it is the key to the greater plan of government irrigation, as to this section of the Western Slope.

The waters of the San Luis Rey will undoubtedly be impounded at Warners' Ranch by a government dam. The present canal, enlarged, will probably bring them to the Von Seggern valley, when the present dam, increased in height from 80 to 150 or more feet, will create an immense storage and distributing reservoir. Other natural sites within a radius of five miles may be utilized as needed, all so located as to offer to Escondido at first hand, their stores of both water and electric power which may be utilized over and over again within her zone of influence.

Now the Escondido valley lies like the palm of a hand, the fingers, adjoining valleys, greater or less in altitude and each excelling in one or more products. Within a few miles may be raised everything worth while and of quality averaging high. More astute and enterprising communities have for years pieced out orders for their well advertised brands of products, with those of Escondido, to the public's satisfaction. We opine that ere long this thing will cease. The public will yet learn where to get its Julian and Palomar apples, San Pasqual alfalfa, Bear Valley honey, San Marcos hay and grain, Guijito beef, Poway dried fruit, Pala gems and the highly prized grapes, raisins, dairy products and poultry which pour out an ever increasing stream from this prolific region. "Escondido" will become a household brand.

Another thing little known is the fact that the best route from Yuma to the Coast is by the San Luis Rey gorge and the best route for a railway from Los Angeles to San Diego, all things considered, is via Escondido. As it is she is off the main line of travel, and fortunately, too, for she is still unboomed and unspoiled. Quiet and patient experimenting have demonstrated her possibilities. Her citrus and deciduous belts, her grain, alfalfa and vineyard lands, her gold bearing ledges and her bee pastures are all well known and are open for inspection. A man knowing just what he wants ought to be able to find it in the "Sun Kissed Vale."—H.

TOPICS FOR GRANGE DISCUSSION.

The Tulare Grange has outlined its topics for the remainder of the year. The next meeting, Sept. 16, "Shall the U. S. exclude or restrict immigration?" Oct. 7, "Duty of Fourth Degree members to the National Grange." Oct. 21, "State legislation of importance to farmers." Nov. 4, "How may farmers of this locality develop resources of their farms." Nov. 18, "Bridge building." Dec. 2. "To what extent should the Grange urge farmers' interests in Congress?" Dec. 16, "If the U. S. builds reservoirs, how should water be allotted?"

San Francisco Markets.

San Francisco, Sept. 13, 1905.

Dairy.

The supply of butter has materially increased, but with the precentage of fancy small, the market maintains a steady tone at practically the same quotations as last week. Storage is being rapidly disposed of, which prevents any immediate increase.

BUTTER—Per lb:

Creamery, fancy	26 @27
Creamery, good to choice	24 @25
Dairy, choice	21 @23
Store	17 @18

There is an increased demand for cheese, giving higher quotations and a firm feeling to the market.

CHEESE—Per lb:

Cal. Creamery, mild, new, extra	12½ 14
Do, mild new, choice	10 @11
Young America	12½@13½
Eastern	15 @17

Eggs.

There is marked activity in the egg market and under light supply quotations have materially increased.

EGGS—Per doz:

Ranch, selected large	35 @36
Ranch, good to fancy	30 @33
Store	Nominal
California storage	25 @27
Eastern, extra	25 @26
Eastern, firsts	22 @24
Eastern, seconds	20 @21

Poultry.

There is an upward tendency in the poultry market with quotations somewhat higher.

POULTRY—Old Roosters, per doz, $4.50@5; young Roosters, $5.50@7; Fryers, $3.50@4.50; Broilers, $2.50@3.50; Hens, small, $4.50@5.50; large, $6@7; Live Turkeys, per lb., 19@22c; Spring Turkeys, 22@24c; Ducks, old, $4.50@5.50; young, $4.50@6.50; Geese, per pair, $2; Goslings, $2@2.25; Pigeons, per doz, old, $1.25@1.50; young Pigeons, $1.75@2.25.

Fresh Fruits.

Apples, per box, fancy, $1@1.35; common to choice, 40@75c; Crabapples, per small box, 75@85c; large, $1.65@1.85.

Figs—Per box, Black, 40@85c, as to size of package; White, 25@50c.

Pears—Per box, Bartlett, 75c@$1.75; other varieties, per box, 35@75c.

Peaches—Per small box, 35@65c; carrier, 50@75c; open boxes, 50c@$1.25.

Plums and Prunes—Per small box or crate, 50@85c, as to variety; open boxes, 65c@$1.25.

Quinces—Per box, 40@60c.

Table Grapes—Per box or crate, Seedless, 50@75c; Sweetwater, 40@50c; Muscats, 40@80c; Blacks, 35@65c; Tokays, 65c@$1; Isabellas, 65@90c; open boxes, 50c@$1.25, as to variety.

Wine Grapes—Per ton, Zinfandel, $20@24.

Pomegranates—Per small box, $1.

Cantaloupes—Per crate, 50c@$1.25; Watermelons, per doz, $1@3; Nutmeg Melons, per box, 25@50c.

Blackberries—Per chest, $2@3.50.

Raspberries—Per chest, $5@7.

Strawberries—Per chest, Longworths, $5@7; large varieties, $3@5; Santa Clara, $6@8.

Huckleberries—Per lb: 4@6c.

CITRUS FRUITS—Per box: Oranges, Valencias, $2.50@4.50; Lemons, $2.50@4.50; Limes, $5@6; Grapefruit, per box, $1.75@2.75.

Vegetables.

VEGETABLES—Tomatoes, per box, 25@65c; Green Peppers, per box, Chile, 25@50c; do Bell, 25@50c; Okra, per box, 25@50c; Beans, per lb, Green, 2@2½c; do, Wax, 2@2½c; Lima, 2@3c; Garden Peas, per lb, 3@4c; Cucumbers per box, 25@40c; Summer Squash, per box, 30@40c; Egg Plant, per box, 40@60c; Garlic, per lb, 5@5½c; Green Corn, per sk, 50c@$1.25; per crate, $1@$1.25; Marrowfat Squash, per ton, $15@20.

POTATOES—Per ctl: River Burbanks, 50@70c; Salinas Burbanks, 85c@1.10; Early Rose, nominal; Garnet Chile, nominal; Sweet Potatoes, River, $1@1.35; Merced, $1.50@1.65.

ONIONS—Per sk, Yellow, 65@90c.

Dried Fruits.

The high prices prevailing for dried fruits have checked the demand to some extent but dealers are holding firm and the general market maintains strong tone at firmly held rates. Prunes are strong with offerings scarce.

DRIED FRUITS—Prices for carload lots, f. o. b. at California common shipping points, in bags, are per lb, as follows:

Apples—Evaporated, fancy, 7¾@8c; choice, 7¼@7½c; standard, 6½@6¾c; Sun Dried, nominal.

Peaches—Crawford, fancy, 9c; choice, 8¼@8½c; standard, 8c; Muirs, fancy, 9½@10c; choice, 8½@9c; standard, 8¼c.

Prunes—Sack basis, f. o. b. For boxed goods add ¼@½c; four-size basis, 3½@4¼c; old crop, 2¾@3½c.

Pears—Bartlett, unpeeled halves, fancy, 12c; choice, 9@10c; standard, 7½@8c.

Apricots—Royal, fancy, 9½@10c; choice, 7¾@8½c; standard, 7¼c; Moorpark, fancy, 12c; choice, 8½@10c.

Figs—Per lb., White, 10-lb. bxs, fancy, 60c; choice, 55c; standard, 50c; Layers, 50@65c; bulk, fancy, 4c; choice, 3¼c; standard, 2¾c; ungraded, 3½c.

Honey and Beeswax.

HONEY—New Crop, Comb, per lb., 10@11c; Extracted, Water White, 6@6½c; Light Amber, 5@5½c; Dark Amber, 3@4c.

BEESWAX—Per lb, 26@28c.

Hops.

The price of desirable old crop is nominal at 14@16c per lb., according to quality.

Beans and Seeds.

BEANS—Prices per ctl. for sound selections; Large White, $2.60@2.85; small do, $3@3.75; Pea, $3.25; Limas, $5.50@5.75; Red, $6.50@8; Pink, fancy, $3.50@3.75; recleaned, ordinary to choice, $2@2.50; Bayos, $4@4.25; Blackeyes, $3.75@4; Red Kidneys, $4@4.50; Horse Beans, $1.85@2. Rain-damaged lots of all descriptions offering from 50c to $2 a cental below foregoing figures, according to condition.

DRIED PEAS—Prices per ctl: Niles $2@2.25; Green, nominal; Field, $1.75@$2.25.

Live Stock.

CATTLE—No. 1 Steers, 6½c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5@5¼c; second quality, 4¼@4¾c; third quality, 4c; Thin Cows and Heifers, 3@4c, Bulls and Stags, 2@4c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4¼@4¾c, gross weight; medium, 3¾@4c; heavy, 3½c gross weight.

SHEEP—Per lb: Wethers, No. 1, 3½@4c, gross weight; Ewes, No. 1, 3@3½c, gross weight.

LAMBS—Suckling, $2.50@3 per head, or 4¼@4¾ per lb. live weight.

HOGS—Per lb: Hard grain fed, weighing alive 80 to 130 lbs., 5½c; 130 to 250 lbs., 5¾c; 250 to 350 lbs., 5@5½c rough heavy, 4@4½c; common, 3½@4c.

Hay and Feedstuffs.

HAY—Per ton: Wheat, $9@14; Wheat and Oat, $9@12.50; Oat, $6.50@11.50; Barley, $7@9; Clover, $7@10; Alfalfa, $6@9; Stock, $5@6..

FEED CORN MEAL—Choice grades, per ton, $30@30.50.

STRAW—Good to choice, per bale, 25@40c.

FEED—Mixed Feed, per ton, $23@24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $22.50@23.50.

CRACKED CORN—Choice stock, per ton, $30.50@31.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $26@29.

GROUND BARLEY—Per ton, $21@23.

COCOANUT CAKE—In lots of 10 tons, $20.50; 5 tons, $21; less quantity, $21.50. Prices are mill rates and are subject to change without notice.

Flour and Cereals.

FLOUR—Net cash, Family, Extra, $4.80@5.10 per bbl; Baker's Extra $4.70@4.90; Oregon and Washington, $3.80@4.60.

WHEAT—No. 1 Shipping, per ctl., $1.30@1.35; inferior grades, $1.15@1.30; White Milling, good to choice, $1.35@1.45 for new and higher for old.

BARLEY—Choice, No. 1 Feed, $1@1.03¾; some fancy grades up to $1.05; common to fair, 95@98¾c; inferior grades, 85@93¾; Shipping and Brewing, $1.07½@1.10; Chevalier, nominal.

OATS—Good to choice White, nominal; Red, $1.35@1.42½ for choice to fancy; $1.15@1.32½ for common to fair; Black, for seed, $1.40.

RYE—Good to choice, per ctl, nominal; new, $1.45@1.50.

CORN—Good to choice, per ctl: California, new, large Yellow, $1.40@1.45; small do, $1.55@1.62½; White, $1.37½@1.42½; Eastern, Yellow, $1.40@1.42½; White, $1.40@1.42½; mixed, $1.40.

CITRUS MARKETS

The sales of oranges continue most satisfactory, though all prices reached at present are hardly equal to those of a few weeks ago. The highest noted during the past week has been in the neighborhood of $7, but that only on a few boxes. Some sales of indifferent fruit run as low as $1.95.

New York.

The total offerings at Monday's sales were four cars. Prices on fancy fruit were, if anything, lower than formerly, the highest obtained during the day being $6.45. The lemon market continued favorable, the top price of the day being $7.37 for 360 size, one car selling at that figure. Averages secured were, fancy, Old Mission, $6.29; choice, $5.38; Blue Seal, A. C. G. Ex., $4.95; California Sunshine, xf, Redlands, $4.30; Standards, O G C A, Redlands, $3.50. Grapefruit ranged from .50 per box up to $2.85. Lemons, Leffingwell, LLL, xf, $7.37; Leffingwell, EEE, averaged to $5.25.

Three cars oranges sold and one car lemons sold at Wednesday's auction, but little interest being displayed by buyers. Weather was unfavorable. Market easy. Valencia averages were: Blue C, xf, Riverside, $4.10; Red C, xc, Riverside, $3.50; Halo, fy, $4.25. In lemons, Rialto Girl, $6.12 was the highest price reached with an average for the car of $5.88.

Only one car of oranges sold at Wednesday's auction. It was a fine car of Old Missions, running from $4 to $6.95.

Boston.

One car Valencia oranges and one car of lemons were sold on Monday, while at the same time eleven cars of deciduous fruits sold. The oranges commanded a range of $3.30 to $5.15. Lemons brought $3.40 to $6.30.

Tuesday's auction showed a decline of ten to fifteen cents. Only one car of Valencia oranges were sold. Price ranged from $2.75 to $4.00 per box.

Market was somewhat easier, two cars of Valencia oranges being offered. They ranged from $2.50 to $4.60 per box. One car of California lemons sold from $4.35 to $6.25, but few reaching the outside figure. Little grapefruit was sold, all bringing less than $2.

GREEN DECIDUOUS FRUITS.

Sales in eastern markets continue remunerative. Seven cars in Chicago sold on Tuesday for from $1059 to $1340 per car.

In New York sales of Lodi grapes aggregated $1615, and another $1634.

Averages prices on boxes in Chicago on Tuesday were: Salways, 45 cents; Bartletts, $1.90; Black Prunes, 60c; Muscats, 80c; Tokays, $1.32; Kelseys, 90c.

The poor cows in our dairy herds should find their way to the butcher's block, and those that are worthy of a place in our herds should have the most considerate care. Instead of the 125 pound cow, they should give place to cows that will produce at least 250 pounds.

The weather and crop conditions for the week ending September 11, are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

General Summary.—Nearly normal weather conditions prevailed throughout the State during the week. High fogs were frequent in the coast sections and light rain fell in San Francisco and vicinity Sunday night and this (Monday) morning.

Hop picking continues and will be completed in some sections this week; the yield is reported average in most of the yards in the Wheatland district and very good in Sonoma county and other places. Bean harvest is well under way and the outlook continues good for a large crop in many sections, in Lake county the yield is quite satisfactory and large quantities are being canned. Sugar beets are above average in the south, but rather light in the central section. The fourth crop of alfalfa is nearly ready for harvest in the San Joaquin valley. Grain threshing, sacking and shipping are still in progress in a few places and hay baling is not quite completed. Corn and potatoes are doing well. Dry feed is still plentiful in most sections and cattle are in good condition.

Grape harvest is progressing rapidly and heavy shipments continue. Raisin making is well under way in the San Joaquin valley, where the crop is reported lighter than usual, but the grapes are of excellent quality. Wine grapes are yielding very well and large quantities are going to the wineries. Deciduous fruits are nearly all gathered and drying is progressing. Apples are reported in unusually good condition and a large crop is probable. Oranges give indications of the largest crop for several years. Guavas in Southern California are yielding an enormous crop. Walnuts will be of good quality, but the yield will fall below average.

Eureka Summary.—Cloudy and foggy along the coast; unusually dry and warm in the interior. Threshing oats practically finished. Peas fair; potatoes light; other vegetables abundant. Apples are being marketed in moderate quantities.

Los Angeles Summary.—Much cooler week benefited crops. Citrus fruits are progressing nicely. Some dry plowing is going on. Threshing is about finished; in some localities the yield is good. Irrigation water is plentiful.

The R. F. Wilson Mfg. Works of Stockton, whose advertisement appears in this issue, is one of the old reliable firms of the San Joaquin valley and we take pleasure in noting its prosperity. Only this week the factory has completed a contract for the Woodbridge Vineyard Association which called for sixty-five tanks with a capacity of 550,000 gallons. Mr. Wilson is one of the pioneer manufacturers of the State and is in touch with the lumber trade of the coast in a way which enables the manufacture of tanks and windmills at rock bottom figures. Transportation is also a factor for his factory practically on the Stockton water front, making water transportation thus giving lowest posible cost. Write the company for information

BREEDING UP.

The astonishingly rapid rate at which livetock improvement can be made by the use of pure bred sires has given the common farmer and stock raiser the advantage of a cheap start and upon a basis of profit from the beginning. It is this breeding up or grading up that has been the foundation of the universal live stock improvement that has been going on throughout the country for years.—Holstein-Fresian Register.

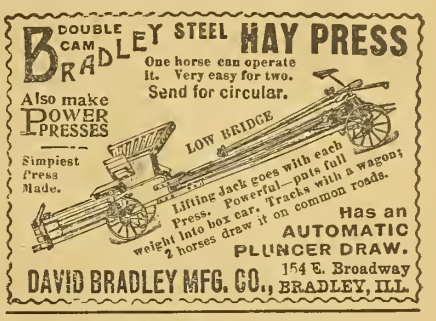
Do not let an animal run down before you begin to think about treating it. Constant care and attention are amply repaid in lack of sickness.

COALS TO NEWCASTLE.

One of the advantages of the new San Pedro and Los Angeles railroad to this section was made apparent last week when Mr. A. H. Snow, Utah's famous peach man, was offered an extraordinary price for his peaches by a buyer for the Los Angeles market. The Los Angeles man insisted that he wanted twelve to fifteen carloads of Utah peaches, claiming that the quality and flavor of the Utah article was superior to the California product. He also stated that Los Angeles is prepared to use seven carloads of Utah potatoes daily. Now is the time for Utah farmers and horticulturists to get in and capture this market.

* * *

The above is from the Desert Farmer and reminds us that it is in order to ask why don't California grow its own spuds and peaches. We don't blame the Utah farmers for carrying their "coals" when they can get a good market, but the idea that our own growers will let produce—especially peaches and potatoes—come from across the range is galling.



IN WOMAN'S BREAST

ANY LUMP IS CANCER

Any tumor, lump or sore on the lip, face or anywhere, six months, is cancer. They never pain until almost past cure.

THREE PHYSICIANS OFFER $1000

If They Fail to Cure Any Cancer

Without KNIFE or PAIN AT HALF PRICE for 30 days. Not a dollar need be paid until cured. Only infallible cure ever discovered. ABSOLUTE GUARANTEE.

Best book on cancers ever printed, Sent FREE with testimonials of thousands cured without a failure. A Pacific island plant makes the cures. Most wonderful discovery on earth. Small cancers cured at your home. No X-Ray or other swindle. Write today for our 130-page book, sent free.

LOS ANGELES SAN FRANCISCO

SEPTEMBER 22, 1905

THE GOLDEN ORANGE HARVEST IN A RIVERSIDE ORCHARD.

There are in California over 75,000 acres in citrus groves The product of these groves is something in excess of 30,000 carloads annually, and to transport this great quantity of fruit to the market a tribute of over ten millions of dollars is annually paid to the railroads, and probably nearly an equal amount is paid to California labor in growing and packing. During the heavier shipping season, from the one community of Riverside alone, three trainloads per day are sent out.

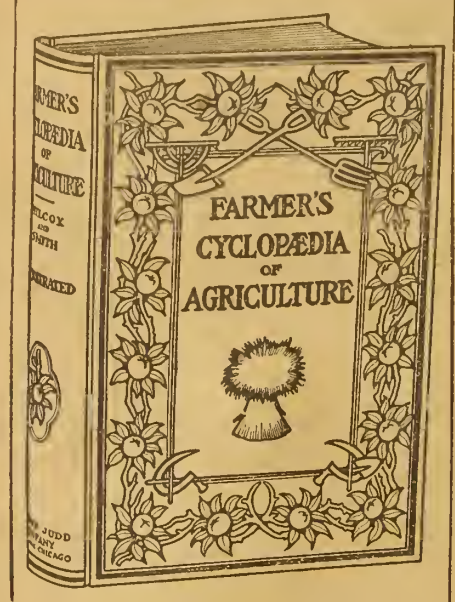
Farmer's Cyclopedia of Agriculture



A Compendium of Agricultural Science and Practice on Farm, Orchard and Garden Crops, the Feeding and Diseases of Farm Animals, Dairy Farming, and Poultry in the United States and Canada

Authors: EARLEY VERNON WILCOX, Ph. D.
CLARENCE BEAMAN SMITH, M. S.
Assistant Editors in the Office of Experiment Stations, United States Dept. of Agriculture

The World Moves

and whoever would not be left behind must lay hold on every means that enables him to move with it. As a basis of one's efforts nothing is more essential than the possession of a good work of reference

Adapted to the Conditions Peculiar to California and Adjoining States

The Farmer's Cyclopedia embodies in its many articles, most of the results of years of painstaking work at the California and neighboring State Agricultural Experiment Stations. It is thus, in effect, both a digest of local and state experience, and a compendium of general knowledge, all of which will prove of indispensable helpfulness to everyone in this section.

The Last Twenty Years of Progress

have measured more changes and recorded more advances in every branch of agricultural science than have been achieved during the hundred years preceding. During all these years no reference book adequately covering the subject has been issued.

The plan of this work is most comprehensive. Every article has received the most careful preparation at the hands of the authors, who have enlisted the co-operation of the highest authorities in the various departments. The greatest educators of the world, representing every branch of agriculture, here unite in one immense faculty to present directly and plainly the pertinent facts of their specialties. Every statement is authoritative and absolutely reliable.

If you wish to know about field crops, garden vegetables, fruits, nuts and other economic plants, farm animals, dairy farming, poultry, also manures, fertilizers, principles of feeding, soils, drainage, irrigation, spraying, veterinary medicines, etc, etc, it is here. Everything concerning farm matters is treated with great thoroughness, though without undue fullness. We claim for it the unique distinction of presenting for the first time, in a carefully arranged and perfeetly accessible form, an accurate summary of every subject of interest to farmers, etc.

Over 6000 Topics Indexed
A Wealth of Illustrations

An important part of this work is its very complete and elaborate index, with cross-references under both scientific and eommon names, so that any information wanted can be found at once. There are between 6000 and 7000 topics covered in these references, making the most perfect Index to agriculture ever attempted. It contains 700 royal octavo pages (9½ x 7 inches) and nearly 500 superb half-tone and other original illustrations. Type, paper, printing and binding are all in the highest style of the bookmaker's art, worthy alike of the well-qualified authors, the enterprising publishers, and the industry of agriculture.

PRICE IN HALF MOROCCO, $4.50

To Cultivator readers we make this proposition:—Fill out and sign the enclosed coupon and mail to this office and the book will be delivered postpaid at once and your Cultivator subscription advanced one year.

Methods for Controlling the Pear Blight

Some Suggestions for Prevention and Eradication of This Dreaded Disease of the Pear Orchards

Probably one of the most destructive diseases which has ever affected the fruit industry of California is the pear blight, or "fire" blight, or zymotic. A peculiarity of the disease, however, is that it is not as regular as some other diseases, being more virulent some seasons than others. In addition, no disease has been found more impossible to reach by remedies than this, notwithstanding the great amount of study which has been given to it by specialists. In fact, practically the only preventive or check which may be given to it is from pruning or cutting out the diseased wood and carefully burning every particle which may contain bacteria. For bacteria it has been proved to be and it has also been found that its means of greatest distribution has been the common honey bee. The bacteria finds its easiest lodgment in the blossoms of the tree. Also in the sweet honey-dew substance which is exuded from the bark to the diseased branches. From the blossoms the disease may extend downward into the branches or run in from lateral fruit spurs so as to do a large amount of damage by the girdling of limbs. When this is done the leaves die because of the prevention of sap reaching them, thus giving from the blackened leaves the appearance of fire having passed through the orchard, whence the name "fire" blight.

The closest study given to this disease has been by Dr. Merton B. Waite, of the U. S. Department of Agriculture, and from him many quotations have been made in which he has given suggestions as to prevention and, so far as possible, cure of trees affected by this disease. More recently, one of the investigators of the Georgia Experiment Station, W. H. Starnes, has issued a bulletin from which we make certain extracts. Some of these do not apply to California conditions, but from them may be suggestions which may give a lesson from the experiments of this investigator. Hence, we give liberal extracts from the bulletin.

For more general information, we quote first regarding the different varieties of blight which have ben studied by Prof. Starnes, but the last mentioned, or number five, is the one which has caused so much loss to California growers:

To the average fruit grower blight is blight—just as "eggs is eggs." But the fact remains that there are at least five different forms or manifestations that might properly fall under the general term pear blight—two of them affecting the leaf, two the twig, and one the entire tree. One of these is produced by a fungus, three by insects and one by a bacterium—only the latter proving fatal. A detailed description of each would consume too much space, so the following brief enumeration must suffice.

(1). **Pear Leaf Blight**—A fungus (Entomosporium maculatum) affecting the leaf. This may be controlled by spraying with a 4-8-50 preparation of Bordeau mixture.

2. **Pear Leaf Blister.**—An insect in the form of an invisible mite (Phytoptus pyri).

3. **Twig Blight (a).**—An insect, Psylla pyricola, or Pear Tree Psylla, slightly resembling the common aphis or plant louse.

4. **Twig Blight (b)**—Also an insect, Xyloborus pyri, or Pear Blight Beetle.

5. **Zymotic Blight.**—Bacillus amylivorus, or the blight of fermentation—also termed fire blight by reason of its virulence. This is the king of blights beside which all other forms are comparatively inoffensive. In character it is, as stated, virulent and aftal, and the utter failure of all remedies except preventive ones, heretofore devised and tested, renders it a scourge to be indeed dreaded. It seems to be universally distributed over the country, and is especially devastating in the South. It has so discouraged our citizens that few growers have planted commercial pear orchards in Georgia of late years, while the pear, even as a garden fruit, is fast disappearing. For a long time the LeConte growers of South Georgia contended that this variety was exempt from zymotic blight, but as far back as 1889 began to realize their mistake. It is now acknowledged that the LeConte will blight as badly as most of the other standard varieties.

Regarding variety most resistant, Prof. Starnes says:

No variety seems absolutely to resist, although Seckel is probably least subject to injury, with Keiffer a good second. Bartlett and Idaho suffer most. As moisture and succulence seem to favor the propagation and penetration of the germ, it may be generally stated that those varieties containing the most water are the greatest sufferers. Hence it is that rapidly-growing varieties or individuals of any variety making a quick abnormal growth of succulent wood are peculiarly susceptible.

The following steps, which are suggested in the bulletin, are given for what they are worth, but, of course, the one on cultivation and especially the one on sodding, number three, are of no value in California other than to show the necessity of not spreading the bacteria by causing the dust and spores or bacteria, rather, to float around the orchard, especially during blossoming time.

Irrigation Without Cost by Tapping the San Joaquin River near Stockton.

1. **Fertilization**—In fertilizing, avoid lot manure or any organic form of nitrogen. Employ a moderate amount of commercial fertilzer only, not very rich in nitrogen, in order that rapid or excessive growth of wood may be avoided. A short-joined, slow growth is preferable, especially after the first year or two.

2. **Cultivation**—Cultivate no more than is absolutely necessary and not at all during the blooming period. It is better to lose some soil moisture than to "stir up the bacilli" and give them an opportunity to be transferred to the tender blossom terminals.

3. **Sodding**—After the orchard is four or five years old and beginning to bear profitably, seed down permanently in some grass adapted to the locality.

4. **Amputation**—As the bacteria chiefly enter through the blossoms and follow the tender shoots downward or inward toward the larger limbs and trunk, it is necessary to cut back, as the malady becomes apparent, so far in advance of its progress that only the sound or unaffected tissue will be left.

5. **Pruning**—It is this feaure as developed by Dr. Waite, more than in all of the other preventive measures taken together, that our hopes of controlling the blight rests: In brief, the Waite method consists of two steps: (1) Formative Pruning—changing the natural tendency of the young tree through the development of a central leader to assume an "excurrent" or pyramidal form, like a spruce by cutting out the leader and thus forcing the development of a "delinquescent" or branching form—each of the limbs possessing practically equal size and prominence. The purpose of the Waite method of pruning is this: Should blight attack the main trunk of a pear having the natural or excurrent form, the entire tree will be sacrificed, or at least fearfully mutilated by cutting out the leader, whereas, if any one of the main branches has to be destroyed when the delinquescent form is given the tree, its symmetry is not materially affected. (2) Spur Removal—taking off those spurs developing fruit buds (as soon as they become apparent in early spring) that happen to grow directly from any one of the main limbs of the tree after it is shaped by the Waite method of pruning, leaving only the fruit spurs on the terminals of the outer branches. This is to confine the point of penetration of the

(Continued on Page 286)

California Horticulturally

By John Isaac, Sacramento, Cal.

THE STATE FAIR.

The State fair last year had degenerated into a pure horse show and the agriculturists were conspicuous by their absence. On the fair grounds the chief attractions were the races, the live stock taking a second place, while the pavilion was used only for a horse show. Agriculture, horticulture and all else were largely ignored. This aroused such a storm of criticism all over the State, that the attention of the legislature was called to it and it was with some difficulty that a sufficient appropriation could be obtained to carry it on again. The new management, profiting by the mistakes of the past, has given a good old fashioned fair this year, in which the agricultural and horticultural products of the State were a prominent feature, while not ignoring other products. Ten counties were represented along the exhibitors, all Northern Californian, and the display of fruit and farm products was a very creditable one indeed. Besides these there were good displays of minerals by the mining counties, of agricultural machinery, while special features every evening at the Pavilion added much to the attractiveness of the whole. There were some good running events, in spite of the elimination of the sporting element, while the stock exhibit was one of the best ever shown here. Altogether the State fair this year reflects great credit on the new management and on Mr. Albert Lindley, the secretary, for his first attempt. With the experience gained from this, Mr. Lindley will make the next State fair one to be remembered, and he has already formulated plans for this purpose. Efforts will be made to have all the counties possible represented and make it distinctively an agricultural fair, in which all branches and all sections will have a fair representation, and it will be shown at a glance what California can do.

* * *

NEW HORTICULTURAL COMMISSIONS.

Strong efforts are being made to get county horticultural commissions organized in some of the northern counties which have heretofore neglected this matter. This is being done largely in order to get somebody with proper authority to undertake the work of fighting the pear blight. The work of Professors Waite and Smith can only be educational, they can show growers how it ought to be done, but there their power ends. When this is done, however, the county board of horticultural commissioners can compel the recalcitrant growers to properly do the work and so prevent their more energetic neighbors from becoming again infested when they have once extirpated the blight in their orchards. Yolo county growers have become alive to the necessity for a strong board for this purpose and a petition signed by many of the leading orchardists of that county has been presented to the supervisors asking for the appointment of the necessary board. Several of the northern counties have been very negligent in this respect, but the necessity of active co-operation, if they would save one of the greatest fruit industries of their sections, has forced upon them the necessity for doing something, and it is probable that we shall soon have as active boards of horticultural commissioners in the north as there are now in the south.

* * *

NEXT FRUIT GROWERS' CONVENTION.

It is not yet decided where the next State Fruit Growers' Convention, the thirty-first, will be held, but it will probably be either at Santa Rosa or Hanford. Strong efforts are being made in both places to get it. The date for holding it will probably be the first week in December. Efforts will be made to make this one of the best conventions ever held in the State.

* * *

A NEW LOCATION FOR SANTA CLARA COUNTY.

The Department of Commerce and Labor, at Washington, which by the way, is in charge of Victor H. Metcalf, a Californian, is having a good deal of fun poked at it on account of its peculiar idea of California geography. In the Daily Consular and Trade Report issued on August 31st, it makes the following startling assertion: "Much the larger portion of the prune supply is from the southern part of California, where climatic peculiarities are extremely favorable for its production. In Santa Clara county alone there are 3,700,000 trees growing on 37,000 acres—100 to the acre." The question asked in this end of the State is—since when was Santa Clara county removed to Southern California. Eastern people have heard so much of Southern California that they labor under the idea that all good things come from the south. But even worse than this is a paper on new citrus creations in the last year book, which gives an account of the new hardy orange, lately invented by the Department of Agriculture, which has nothing to recommend it except that it will stand a climate as rigorous as that of Washington itself. In this paper the writers state that "It is also probable that they can be grown in parts of Washington, Oregon and Northern California." Just think of classifying Northern California with Washington and Oregon and offering us an orange which isn't fit to eat, when we grow the finest oranges on earth, unexcelled by any outside of Southern California. They need some one who knows more about California in Washington.

GRANGE MEETING.

Tulare grange convened in stated session at its hall on Saturady the 16th.

The special committee to consider subjects to be presented, by the representatives of the grange, to the State Grange, which will convene in the city of Napa on October 3d next, reported in favor of the following:

"We recommend the National Good Roads Law as prepared by the National Grange, and introduced in the House of Representatives.

We recommend a revision of the revenue laws of California by which ability to pay shall be the test of obligation to do so. By which realty shall be relieved of its, now, disproportionate rate of taxation. By which the State shall derive its revenue from other sources than direct taxation of real and personal property. By which the recipient of the income not derived from property taxed, shall pay his equitable prorata of taxation. By which a portion of the State's revenue shall be raised by indirect taxation.

We recommend State legislation for the equitable distribution of water for irrigation. For insurance against fire by the State. For life insurance by the Federal Government.

We believe the "Torren's" system of land registration is one of the most meritorious acts of legislation ever enacted in California. Justice to the land owner and purchaser, alike requires it should be enforced with all the powers of the State. Its, heretofore, non-enforcement is a miscarriage of an equitable and just law in this State.

Each of these subjects was discussed separately and a careful consideration given to it, and each approved by itself and all approved as a whole. These several subjects have been considered, studied and approved by subordinate State and National granges, except the subjects of State fire insurance and Federal life insurance. These, being new subjects, received more than usual consideration; but it was conceded, on all sides, that in the well doing and well being of civilized life, efficient fire and life insurance is one of the most essential necessities. In no department in the administration of public utilities are greater wrongs perpetrated than in those of fire and life insurance; by the payment of undue commissions; by the use, by the officers of the companies, for their own speculative purposes, of the company funds; by the payment to themselves of pensions and enormous salaries—salaries many times out of proportion to what any one man can equitably earn; the funds of the companies are speculated and juggled with to the detriment of the insured. No such culpable use of funds and no such exorbitant salaries are allowed, or thought of, in State or Federal administration, and this grange greatly regrets to say, in its judgment, the abuse will not be remedied until fire and life insurance are departments of our State and Federal Governments. Tulare Grange asks the careful consideration of a thoughtful public to this subject.

Mr. and Mrs. F. H. Styles were elected alternates to the State Grange.—J. T., Tulare, Cal.

PUMPS!

Jackson's High Efficiency Vertical Shaft Centrifugal Pump

This pump can be submerged and will run equally as well under water as above it. It is also automatically balanced against up or down thrust. Write for Catalogue No. 12.

BEEKEEPING FOR BEGINNERS.

We have already discussed the importance of great care in marketing honey. Any effort to secure neatness is well expended. Care in grading is most wise. "An honest pack" here, as in all marketing, pays a tremendous profit. Facing a crate with fine, fully capped comb and filling back with dark imperfectly capped sections will never pay. The beekeeper, like any other producer, is most happy and to be congratulated, whose reputation is secure, whose goods are never questioned, for his grading is thorough and every package is honest.

* * *

Care of Honey.—As I have already suggested, the time to sell honey, or any product, is as soon as it is ready, and we can attend to the marketing. We have seen that this is preeminently true of honey.

Yet, in some cases, we can not do this and must hold. In this case, we do not follow the fruit grower, who uses the cellar or refrigerator. He wishes to cool his produce as soon as possible and hold it at the low temperature, to protect against decay. In case of honey, we wish to avoid cold and damp. The cold makes the comb brittle and causes the moisture to condense on the combs, which is further increased in a damp room like a cellar. The honey, even comb honey, will absorb moisture and be seriously injured. Thus honey should, when possible, be kept in a warm, dry room, if for any reason it is desirable to hold it over.

* * *

Gentle Bees.—We have long known of the gentle, amiable disposition of Carniolan bees. These are black bees, much like our common black, or German bees, though they are slightly larger, and each ring of the abdomen of the workers is circled, behind, with whitish hairs. This may be obscure, but when well marked it makes these bees conspicuously beautiful. Like the black bees, the Carniolan race caps the comb with very white cappings, so that the honey is finer in appearance than is that of the Italians, or other yellow races. The Carniolans also build very many queen cells at time of swarming. They are without doubt very desirable bees, but not equal, as to quantity of honey, with the yellow bees.

* * *

Other Quiet Races of Bees.—Above we noted the amiable traits of the Carniolan bees. While looking over the bees already mentioned on the grounds of the Department of Agriculture, with Dr. Phillips, he opened a hive with a Caucasian queen. They were large and fine of form, but shining black in color. They, like the Carniolan bees, seem clearly to be a distinct race of the black, or Erman type of bees. I think that they are beyond question, the most quiet or amiable bees that I have ever examined, although we opened the hive without smoke, and handled the bees roughly, they made no move at all to sting us. We brushed them rudely with the hand, and even pressed them in our fingers with no effect to raise their anger. Here then, we have what Burbank would greatly prize, a variety or natural race that possesses a very desirable trait. Here then, we have just the foundation for success, and will hope that Dr. Phillips will have as good fortune in his breeding experiments with these bees as Burbank has had with his lilies, his plums and his poppies. Indeed, bees are more like plants than are most animals. We can rear them with great rapidity and can get results quickly, so that many tests can be made in a single season. Already Dr. Phillips is producing queens in great numbers. These he takes in small nucleus hives over to Arlington, where he hopes to control mating.

With animals, as with plants, if we take those from widely different places, which as a result have been subject to very varied climatic conditions, change them to other habitat, and cross with those of different habits, instincts and temperment, we may surely expect interesting variations, and it will be surprising indeed, if in countless numbers of queens, Prof. Phillips does not get some that will, like Burbank's Shasta Daisy, combine marvelous qualities of temperament and activity, and become as phenomenal among bees as the great handsome daisy is among flowers.

* * *

The honey crop the present season is light in nearly all the States. Michigan is the only State that claims anything like a full or average product. California, thanks to the unusual cold of the season, offers scarce a third of a crop. All this makes it possible to secure a good price. All should hold for high figures this season.

Black Scale.

Fumigation is now in full swing in such citrus orchards as are in need of this treatment. Incidental to this operation the question is being continually brought up as to the advisability of fumigating an orchard in which the scutellista is colonized. Parties interested from different standpoints naturally hold opposite views; one side claiming it to be an entomological crime to destroy the parasite, the other equally sure that fumigation does not affect the scutellista. Broadly speaking, it is a fallacy to state that gas of sufficient density to destroy the black and purple scales has no effect upon such highly organized forms of insect life as the chalcids caught beneath the tent. On the other hand, the fact that the parasite occurs in an orchard—otherwise sufficiently infested with black scale as to make the necessity of washing the fruit this season a foregone conclusion—should not be allowed to stand in the way of prompt fumigation the moment the condition of the scale warrants success.

Black scale occurs on an infinite variety of host plants and the scutellista is so thoroughly distributed in every nook and corner, that it is fair to assume even if every citrus orchard in the county were fumigated simultaneously, there would, now, be no danger of eradicating the fly.

Just why some orchards should need fumigating for black scale while others have, and are being kept commercially clean by the parasite, is a perplexing question, especially so to the party who has to pay the bill. In the opinion of the writer this state of affairs at the present time is due more to the unstable biology of the black scale than to any vagary or inefficiency on the part of scutellista cyanea. The foregoing conclusions are derived from the following observations.

The progress of develpoment on the part of black scale is governed almost entirely by the host plant upon which it is located.

For example: The writer has found numerous full grown, abnormally developed black scale in the full egg stage upon pumpkins that had not been in existence 90 days.

The larvae of the same brood that had located upon the deciduous trees (pears) comprising the orchard in which these same pumpkins were growing, required approximately twelve months to reach this stage of development.

Again: Horse weeds growing in a gulch forty feet away from a citrus orchard were found to be covered with black scale, eighty-one being counted on one weed in a space of sixteen inches, fifty per cent of which contained pupa of scutellista. One hundred and twenty days would average the life of these annual weeds, yet black scale had completed its round of life in this period and such as were not parasitized had hatched their eggs. In the citrus orchard adjoining this weed patch, while black scale were present, it was very difficult at that time to find scutellista in any form.

Further, the progress of the development on the part of black scale even upon the same variety of plant is very materially governed by the condition of the plant. Black scale is very rarely found in exactly the same stage or condition even in adjoining orchards.

Finally, black scale must positively have reached a certain stage or condition—the production of eggs—before scutellista will oviposit upon it.

In the case of scutellista, in common with other insects of this class, copulation takes place immediately after the adults issue. Very soon after coition the females are ready to oviposit, and judging from the actions of similar insects in confinement, the desire to perform this natural function becomes very urgent; perhaps imperative. It is possible that failing to find a host insect in suitable condition, the impregnated female parasite can live a long time, but in the case of scutellista and black scale this is not likely to occur. The parasite in question, visiting a citrus orchard or nursery and finding that, owing to some physiological disturbance of the trees in that particular orchard the scale is not in condition to receive its attention, has simply to fly to some adjoining orchard, or perhaps to some infested wild growth or shade trees to find scale in condition exactly suited to the purpose of reproducing its kind.

This, in my opinion, is the cause of the phenomena of infested spots in otherwise clean orchards and of infested orchards in otherwise clean districts. That the black scale upon these infested trees would eventually be attacked and destroyed I am sure, but before that time arrives the foliage and fruit will become blackened, and the question before the growers is not whether the parasite will be destroyed or otherwise, but whether the cost of washing the fruit and other losses attendant upon this operation will not in the end equal or perhaps exceed the cost of fumigation.—Fred'k Maskew.

Strawberries for Profit

By J. C. Ostergard, Burbank, Cal.

There is probably no section in the United States where strawberries can be found ripe, out of doors, every day in the year, but in California. On this account the crop proves very profitable. Money comes in not by fits and starts, as is the case elsewhere, but in a continuous stream. The bulk of the crop comes in the spring, decreasing considerably during the summer months, but a very fair crop is sure to be harvested in the fall, if the field is properly managed. Even during our coldest months some berries are marketed.

Because of continuous crop habit and as there is a large and wide market for this fruit, the trade has assumed large proportions. Its value can only be vaguely guessed at, but it probably runs close to the million dollar mark.

To insure a profitable income from strawberries, a suitable soil and climate is, of course, of the highest importance. A deep, rich, sandy loam is best. As to location, a section where the fogs come up frequently, yet do not linger long, is best. That is to say, the air should neither be too hot and dry nor too cold and damp.

* * *

Their Culture.—The variety known as Brandywine seems to be the favorite in some sections, being a robust plant and a strong grower, with a berry of good size, fine flavor and a brilliant appearance. They continue in the same patch for about three years and then become unprofitable, no matter what care or fertilization may be given. Generally the soil will be found rich enough for the first year, but where the soil is rather light and sandy, a fair amount of stable manure will be in order. About fifty tons to the acre or less, as the soil may seem to require. This should, of course, be applied and plowed in after the ground has been leveled. If there is a lack of humus in the soil, the plant growth will be weak, the berries small and lacking in color. The second and third year well rotted stable or chicken manure may be applied if it seems to be needed. As long as the plants are making a good growth of dark green leaves, fertilization is apt to do more harm than good.

* * *

Profit.—It cannot be said to rank as high as some other crops, but, on the whole, is very satisfactory. The average gross income is about three hundred dollars per acre, of which at least three-fourths goes for expenses; that is, if you hire everything done, pay for water, cultivation and cost of marketing. Of course, in some cases, the profit may be higher, but if so, there will be cases enough where it will be lower than seventy-five dollars per acre.

* * *

SOIL SUITED TO WATER AND MUSKMELONS.

As these valuable fruits can not be grown on the same soil for a period of more than two or three years, even ranches having good sized fields are forced to rent land or discontinue the business. That is a thing a man seems loth to do after he has once gotten onto the ways of raising and marketing melons.

A rich, sandy loam is best suited to the perfect growth of the watermelon. If irrigation can be resorted to the soil need not be over two feet deep. But where there is no water to be had for irrigation, the soil should not be less than four feet deep. In order to insure good results, the deeper the better. When you go out to find a piece of land, take your spade with you and dig holes here and there. Surface indications count for little or nothing. It is the deep soil that is to sustain the plant during the hot weather of the summer months.

* * *

For Muskmelons.—The soil required is the same as for watermelons, excepting that it should be richer and finer. They will not thrive on as sandy land as will watermelons. In short, the soil must be richer and more compact, and yet not be inclined to bake.

* * *

Tomatoes.—That the recent hot spell put an end to the tomato blight, as was suggested in the last number of this paper, has been more particularly verified. While tomatoes may still be seen dying with the disease, it will be noticed that they are the ones that were afflicted before the hot spell.

A year or two ago an eastern agricultural paper contained an article by a tomato grower, wherein he stated that a certain field of tomatoes was suffering heavily with the blight. Adjoining was a mixed field of corn and tomatoes, with no blight present. He simply mentioned the facts in the case without attempting to explain the reason. The editor made no comment, it being evidently a case similar to the one experienced by the young medical practitioner where a certain treatment promptly cured the blacksmith but as promptly killed the tailor. He made a note to the effect that this was one of those mysterious conditions that brought life to a blacksmith but held certain death to a tailor. I am free to confess that I was not at the time able to solve this apparent riddle, but since heat destroys tomato blight, and as it is hotter in a cornfield than in the open, we see at once that it was this increased heat that saved the tomatoes. It may be well to remember this lesson and practice it next year, planting alternate rows of tomatoes and corn, with the tomatoes on the sunny side.

* * *

Tomato Worm.—Nearly every year tomato growers lose a large percentage of their tomatoes by this pest. No remedy has yet been effective. I would suggest to stick four-foot lath into the ground, distance about sixty feet; if this is done, the mocking and butcher birds will be given a perch from where they can see and apprehend the pest.

* * *

Continue to plant winter tomatoes, Early Rose potatoes, peas and beans, but only in the most sheltered sections.

RUBBING IT IN.

"How's things in your division?" asked the weather bureau clerk.

"On the bum," replied the agricultural department official. Every cheap joker in the country is writing us for information about grafting."—Houston Chronicle.

Outlook for Citrus Industry

The Season of the Year Has Something to do with Prices, but Adaptation of Varieties to Location Has More.

In the last issue we referred to the fact that a certain season of the past year had proved almost disastrous in its return for oranges, which was also true of the same months in the year prior. It may be of interest to note the prices which ranged from month to month during the season. To that end we quote below figures which were obtained by the San Antonio Fruit Exchange for its fruit during the season of '03 and '04. While this season is almost a parallel of the past season, so far as figures can be secured at the present time, we do not think that it indicates any invariable rule which can be depended upon every season. The fact that January shows the lowest sales in these two years does not prove that the next year the same will follow. However, the conditions which we noted in the last issue may compel extra heavy shipping or weather conditions may seriously affect fruit at that time.

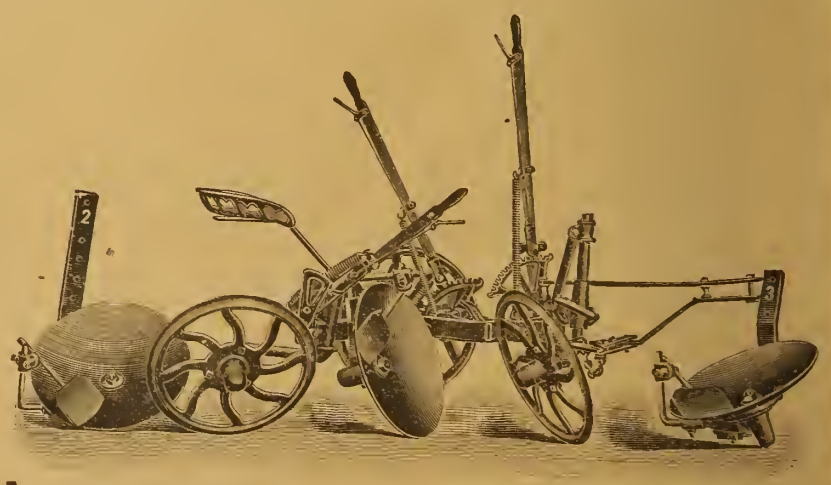
Here are the figures and they may be taken for what they are worth. November navels brought to the San Antonio Fruit Exchange $1.59 per packed box. The returns to the grower would be about thirty-two cents less than that, as is the case in the figures following: December navels brought $1.43; January, $.88; February, $.97; March, $.99; April, $1.12; May, $1.44; June, $1.61.

If anything, this year's figures will show greater difference between June and January shipments in this, that June will be higher. Now, while we note that this is no proof of next year's monthly returns, we do feel that it is an indication which should influence somewhat the grower's actions when his fruit begins to show some indication of dropping during the months of January and February. That is, we believe the grower can well afford to allow some of his fruit to drop during those months rather than glut the market with excessive shipments when it will not carry all the packing houses are compelled sometimes to forward. This holding back at the time and permitting some of the fruit to go on to the ground for fertilizer will probably bring more net returns to the grower and considerably less expenditure for boxes, packing, hauling and freight.

One Ontario grower told us that while his neighbors were forcing off the earlier fruit from orchards which showed a tendency to drop, he held and allowed that which would to drop and marketed his sound fruit later at a higher net price per acre than that secured by his neighbors. Now, while it must be confessed it takes some grit to see good looking, sound oranges dropping, if the grower would only quietly permit it to go on and then accept the greater money at the end of the season, he certainly would be happier and more well-to-do.

* * *

One thing peculiar about this season is the fact that the usual satisfactory returns received by the more inland valleys have been exceeded by the closer-to-the-coast sections. In fact, taking all citrus fruits, we believe it safe to say that the sections north and south of Los Angeles, which have usually given indifferent returns, will this year make a showing on their total shipments of the season of better net returns than any of the premium-winning navel orange growing valleys. This has been in part largely owing to the fact that



The Emerson Disc Plow

Is Far Ahead of Any Other Make

Note the points of superiority: **Levers** controlled from the seat; turns a **square** corner; instantaneous acting lever; number of discs easily **reduced** or **increased**; **dust-proof** and **oil-tight** bearings. Rear lever provides ample depth of furrow in opening land and when on the road. It is **compact, strong** and **durable.** We supply these high-grade plows. You make no mistake in purchasing of us. Our catalogue gives a full description of the **Emerson Disc Plow**, together with many other farm implements and utilities. **It is sent upon request.**

Newell Mathews Co. 200-202 NORTH LOS ANGELES STREET LOS ANGELES, CAL.

Selling Agents—Bird & Beebe, Anaheim; Whittier Implement Co., Whittier; Twomey & Smith, Pomona; Riverside Implement Co., Riverside; H. Gregory, Redlands

the section in question has been the larger producer of Valencias and lemons, and Valencias and lemons have broken the "world's record" this year and brought returns which were almost fabulous. This, in the case of lemons, is especially satisfactory, for the lemon growers for the last few years have had up hill work in attempting to get a living price for their goods. As noted in last week's paper, one association, the San Dimas, shipped sixty cars for which they received $60,000. Other shippers have been heard from who have secured close to $7 per box for the entire shipment.

This question of lemons and Valencias and of navels, brings us to discuss for a moment the one point of locality for the different varieties of citrus fruit. For instance, the Washington navel orange has usually been considered to grow to its sweetest and best along the foothills from the Duarte-Monrovia section on the east through San Dimas, North Pomona, Uplands, Cucamonga, Highlands, Redlands, and on the south along the Arlington Hills above Riverside. This is not saying that other sections do not grow nice navels, but that is a section in which the bulk of the best fruit is grown.

On the other hand, with lemons, while they are grown in the entire section mentioned as favorable for navels, we believe it safe to say that the bulk of the finest grade of lemons are grown near to coast influences. For instance, at Santa Barbara, Montecito, Santa Paula, Whittier and sections of Orange county, there have been forwarded some of the finest grades of lemons and in the best of shipping condition that can be produced in the State. We believe this is generally conceded, though some of the producers of lemons in the more inland foothill sections have claimed equal advantages. But we believe there is greater danger of shriveling of the cured fruit and that the acid content of such fruit is not generally equal to the best of that produced near the coast.

This year we have heard the theory advanced, and believe it good, that the Valencia orange requires practically the same conditions as does the lemon. For the first time, we have heard a prominent Riverside orange grower say that while he still claimed for his section the peer of any place in the world, as a navel producer, he must admit that the best Valencias and the highest selling fruit had been, as a rule, produced nearer coast influences than Riverside.

This is not mentioned to knock or in any way detract from any section, but to call attention to the fact that exceptionally fine fruit, well-packed of its kind, is reasonably sure to command a living price and to take the market at any time. The indifferent fruit costs just as much to pack, to handle, and to ship, and for other expenses as does the best of fruit. Then, is it not a good lesson for the owner of land in Riverside, or Redlands, Highlands, Uplands, or North Pomona, to devote such land to the growth of that for which it is pre-eminently fitted? To illustrate: While conversing with the manager of one of the largest packing houses in Redlands recently, we asked what was the percentage of the various grades of navels, as the fruit came in ordinarily from the orchards, and he replied, "Fancy, about thirty per cent; choice, fifty per cent; standards, fifteen per cent, culls, five per cent." Asking the same question in another section which ships several hundred cars of oranges, we quickly received the response, "We have not shipped a single fancy navel from this house since January and of extra choice for the entire season not over two per cent, with only about fifty per cent of choice, balance standards and culls." That was as to navels, of course. In Valencias, the same section produced some of the finest fruit grown, that will grade much higher than for the navels. Now then, in the future, if planting be done, is it not the best of wisdom for this section that produces extra fine Valencias, and, we may add as well, lemons, to let the planter choose those varieties; and the planter individually, and California in general, will be enriched by such action.

Of all the expensive teaching which experience has given to California, this experimenting to find productions adapted to localities has cost the State the greatest amount. It has often been used as an illustration of the fickleness of mankind to refer to examples of planting of oranges, followed by olives, which in turn were uprooted and followed by apricots, the 'cots later to give way to alfalfa, which latter proved a complete success. But rather than an example of fickleness, we take it as an example of the lack of judgment of the first planters in their choice of trees for those conditions.

CITRUS FRUITS

By C. A. Day, Pasadena

RED SCALE.

The red scale is pretty widely distributed throughout the citrus fruit growing districts of Southern California. It belongs to the armored class of scale, but differs from some other varieties in that it lays no eggs. The young are born, or in other words, the insect is viviparous, therefore, any treatment that will destroy the old scale, will destroy the young also.

Its main breeding season is during the warm weather of the summer. The period of generation is about 40 days. It also breeds to some extent through the winter and spring, with a somewhat longer period of generation. The main breeding season begins in the month of June, and with a warm fall, is active until the first of January. Like other scale insects, it chooses certain varieties of trees, shrubs and vines which it attacks in preference to any other. It readily attacks all citrus trees, but it prefers the lemon and grapefruit. It comes to infect the orange, but is slow in gaining a foothold in the orange orchard, but when once well established in the orange orchard it becomes a serious pest.

Aside from citrus trees its favorites are the camphor tree, certain varieties of roses, some varieties of palms and it is sometimes found on a few other species of shrubs and plants.

On the citrus tree it locates on the fruit, foliage, new and old wood, and trunk of the tree. When located on the fruit it will continue to live and breed long after the fruit has been detached from the stem.

* * *

Spread of the Scale.—The young larvae have the power of locomotion, but very soon permanently locate on some part of the tree. It is distributed from one orchard to another by means of infested fruit, nursery stock, picking sacks and boxes, and is probably carried by birds and insects. It does not immediately infest the whole of even a lemon orchard, but located upon a single tree, gradually spreads to the surrounding trees, and when not interfered with by fumigation or spraying, will require two or three years to thoroughly infect an orchard of considerable size.

* * *

Parasites.—There are no parasites in California that effectually control the red scale. Several of the ladybirds feed to some extent on the larvae and at least two species of the chalcid fly attack the mature scale, but none of these are effective.

In experimental work the writer secured a year ago from Orange county, lemons infested with red scale. These lemons were placed in a close glass jar. A considerable number of the golden chalcid fly were bred out from the scale. The same chalcid fly was found attacking the red scale at Pasadena, but had no perceptible effect in controlling the red scale even on trees that had not been treated.

This scale has long been a common pest in the Levant and in China and Australia. Its probable home is in the Oriental countries and that is where we should look for an effective parasite. It is to be hoped that the State Horticultural Commission will eventually succeed in finding and introducing an effective parasite for the control of this scale pest.

* * *

Injury to Tree and Fruit.—The scale feeds on the sap and is a draft on the resources of the tree. The infected fruit is not marketable and even where the scale on the fruit is destroyed by treatment, the fruit, especially lemons, is injured in appearance and will not pass as first class fruit.

* * *

Treatment.—There is great difference of opinion among growers of citrus fruits as to the best methods of treatment for the control or eradication of this scale. Some are strong advocates of spraying, while others as strongly favor fumigation. I am sure that no one will claim that spray of any kind will eradicate the red scale, and all that can possibly be claimed for this method of treatment would be to control or reduce the scale to a point where it would no longer be injurious to the tree or fruit. Spraying is cheaper than fumigation and must be applied at least once a year, and where the trees are badly infected, twice a year. Spraying is effective when applied at the beginning of the breeding season of the scale, say in June.

Where the orchard is sprayed in the fall, usually in September and October, the scattering scale left alive will continue to slowly breed through the late fall, winter and spring, and a considerable stock of scale will be on the trees at the beginning of summer, and these will quickly restock the tree, and, further, where the infection only includes a part of the orchard or where there are adjoining orchards that are not infected, there will be a further spread of the scale during the principal breeding season of the insect. The effort to apply the spray at a time when it will be in a measure effective on the red spider, black, red and other scale, has resulted in the applying of the spray in the fall. The question would here naturally arise as to whether a single spraying in June would be sufficient for red scale. From experience and observation, I should answer no. It will always be necessary to spray in the fall, giving an extra spraying at the beginning of the summer. The lemon tree will stand a stronger spray than the orange and when spraying for red scale the full limit as to strength of spray shold be used.

The difficulty in spraying for red scale is that the scale, when well established, infects the entire tree, including the interior and the trunk of the tree, and it becomes impossible to reach and destroy all of the scale.

* * *

Fumigation.—Fumigation with cyanide for red scale, when properly applied to a single tree, will destroy all of the scale, but in the fumigation of the trees of an orchard of any size it is doubtful if a single fumigation would destroy every living scale in the whole orchard. The scale on infected fruit lying on the ground under the tree that is fumigated, would probably escape injury, as the gas under the tent near the ground is of less density than in the rest of the space enclosed by the tent. In fumigation the full limit of material and the right proportion of water should be used, the tent should be whole, well down to the ground and should remain on the tree one full hour. A fumigation of this character should last for at least two years.

I favor the fumigation of citrus orchards, excepting large seedling trees, where the expense would be prohibitory, at least every two years to hold in check red, yellow and greedy scale.

* * *

YELLOW SCALE.

The yellow scale is very much like the red scale in structure, but varying from the red in color and habit of infesting only the foliage and fruit of the tree, rarely being found on the wood. This scale is sometimes held in check by parasites, but in many cases requires treatment similar to that for the red scale.

HAVE YOU MADE YOUR WILL?

I make a specialty of wills, and prepare them, in conformity with the laws of any State, at one-third the usual charges. For ordinary wills—as husband to wife, for which the ordinary charge is $10—my fee is $3. Others accordingly. By mail as satisfactorily as by personal interview. Twenty years' experience. Highest references. ***E. C. CAYPLESS, Lawyer, 207 Currier Building, Los Angeles, Cal.***

ROCK GARDENS.

There are two kinds of rock gardens, those built as homes for plants and others put together to have a natural appearance, the latter consisting of immense boulders placed according to fancy and which must necessarily accommodate but a very limited number of plants, unless the garden be of great exetent. The rock garden which is built chiefly as a home for a collection of alpine and low-growing herbaceous plants, may be constructed to occupy a comparative small space, just enough to accommodate those plants of a showy nature. More extensive rockeries to provide a home for every known species at all likely to thrive irrespective of their attractiveness are only necessary in public gardens for educational purposes. A rock-work home is absolutely necessary for some kinds of plants in order to have a source of permanent supply. Among those which it is advisable to grow after this manner are sedums, sempervivums, aubrietas, gypsophila (dwarf), thymus, cerastium primulas, saxifragas, Lithospermun prostratum, edelweiss, Geranium sanguineum, penestemons, dryas and Azelea procumbens.

GINKGO FRUITS.

In California, and quite generally throughout the United States, we grow the Maiden-hair tree and though it fruits freely no one has reported its use for food. John Chinaman seems to relish it, as he does every evil-smelling fruit he can obtain.

The fruit of the Ginkgo is of the size, shape and consistency of a small plum. The fleshy portion, at first a bright green, turns yellow when ripe. The pulp is rich in an oily substance, which at an ordinary temperature is of a butter-like consistency. The quantity of sugar contained in this oil is very small, and the fermentation, supposing it to be easy to ascertain, would certainly yield only a slight proportion of alcohol, the value of which, supposing it could be utilized, would not cover the cost of production.

It is then rather to the oily matter that one's attention should be turned in endeavoring to put the fruit to some practical use. This could probably be obtained by any process applicable to the olive. It must be noted, however, that this oil, in three or four days at most, on exposure to the air, quickly develops a rancid odor, which would certainly be found very disagrecable.

According to certain authors it appears well established that the Chinese willingly eat this pulp, but probably this would not be to our taste. Not that there is anything very astonishing in that, as it would be easy to name numerous other foods upon which we have not the same ideas as the people of the Far East.

But if it does not appear to us that the pulp of the Ginkgo has any chance of figuring in the ordinary fare, it may be otherwise with the seed. This possesses a flavor somewhat like the walnut or hazelnut. The oil it contains, which must be of different composition, does not become rancid like that of the pulp, and it is quite probable that this seed might become quite acceptable as an article of food. In common with the greater part of the conifers, it contains besides the oil a certain quantity of starch, which would complete its dietetic value.

This beautiful Chinese tree is used only for ornamental purposes. It flourishes in deep mellow land, where there is no undue proportion of clay, and shows a hardiness practically absolute, due in part to the decay of its leaves, which renders it almost indifferent to the rigors of the Eastern winter. The propagation is very simple, both by sowing immediately after the fruit is gathered and by cuttings stuck even in the open air at the end of the season.

CHORIZEMAS.

The Australian flora is very rich in leguminous plants suitable for culture in this country, and among the many genera Chorizema is conspicuous on account of its general usefulness and beauty. They have been in cultivation for nearly a century but like many other good old things, not now grown to such an extent as their good qualities warrant. In habit they form a loose bush with long, thin branches sparingly clothed with holly-like leaves, the largest of which are barely two inches long. The flowers are small and bright red, with a yellow blotch at the base of the upper petal. They are borne in long, loose, terminal racemes, both from the main branches and all side branches. The flowering season is midwinter, and the plants keep in good condition for quite three months. After flowering the plants should be cut back and rested until growth recommences, after which they should be given as much light and air as possible. A few years ago these shrubs were quite popular in some parts of California but because they needed a little care were doubtless allowed to dwindle away, until now hardly one may be found. They are well worthy of more extended cultivation.

CYCLAMEN.

Growers of cyclamen obtain the best results by raising new plants every year; still old bulbs can be flowered well if they are treated properly. The cause of bulbs not blooming is generally because they have not had complete rest or, having been dried down too soon after their flowering period last year. To dry the bulbs down so they will flower well next season, you must be governed by the condition of the plants, as there is no set rule to go by. When you see that they have made all their growth and are inclined to rest begin gradually to withhold water; but do not let them get dry enough to wilt as long as any foliage remains on the plants. The chief aim is to have the bulbs commence the resting period naturally; after drying put them away in a dry, cool place until they show signs of life, when they should be taken out and potted, using a soil composed mainly of leaf mold.

Perhaps seedling cyclamen are generally potted in a too heavy soil. Pot them in pure leaf mold with a little sand mixed with it; keep them warm though well shaded; water only when they need it, using water from a barrel or tank to have it warm. Water direct from the hose pipe is too cold for the young roots.

DANGER OF OVERPLANTING.

A certain amount of shade is very desirable in connection with a house, especially in climates like ours where, during a great portion of the year it is more agreeable out doors than it is in rooms; yet it had better be secured by covered verandas than by trees. It ic also more conducivc to health to sit under a covered roof; exposure to evening dews is a well known fruitful source of sickness.

Another disadvantage resulting from surrounding the building with a thicket of foliage is, that it shuts out the views of immediate and distant scenery, as seen from the house, at the same time the house as an object of the local landscape, is completely hidden from view. If the achitecture of the structure has received any study as a work of artistic design, it should in itself form a picture which, to be properly appreciated, must be seen and viewed as a whole, so that its proportions, outlines, elevations and ornamental details may be taken in at one view. Even beds of low shrubbery, if abundantly introduced near the base of a building, will foreshorten the elevation, obstruct the view of the horizontal base line, and seemingly destroy architectural proportions. Many of the finest structures, both public and private, are ruinously shorn of their beauty by careless or ignorant planters, who, in their endeavors to beautify a building, succeed only in concealing those salient lines and projections that give it character and distinctiveness.

APPROPRIATE GARDENING.

A proper connection of the house with its surroundings is the first point to which attention should be given in laying out grounds, as it is the most prominent and leading detail of improvements. A house should not appear to have risen out of the green lawn like a tree. It is necessary that some evidence should be apparent of suitable preparation having been made for the building; at least, a level plaform of more or less width should project from the base line. The groun l line should be level, and all walks should correspond with the lines of the ground plan. Zigzag and curving walks close to the straight lines of a large, of even the most humble building, are directly opposed to beauty or propriety; they are sure evidence of unskilled labor.

WHEN TO GATHER SEED.

The inexperienced will be apt to let their vegetable seed remain on the stalk or vine till it is overripe and consequently lose a large per cent of it. Beginners aim to have every seed ripe before gathering, whereas they should aim to have every seed mature before gathering, which will include the ripening of the great bulk of it, depending on sun and air to fully ripen the remainder. Take cabbage seed as an illustration. If we wait until the whole crop ripens on the stalk, then after a heavy dew or prolonged rain, a large proportion of the seed pods have snapped open as soon as the sun strikes them. If we wait till every onion seed in the head is ripe, the first breeze will shower it on the ground.

Gather cabbage seed either a day or two after the pods have attained the red color, when on breaking they show dark red seed within. Lay the stalks on a tight floor, where sun and air have free access. Gather the onion seed whenever the stock is dead just below the seed head, or when a third of the seed receptacles have cracked open, it matters not how green the stock may be. Spread the seed heads one deep on lath frame, in a dry airy loft. Carrot seed can remain out longer than seed of any other vegetable without wasting. The waste begins on the outer row of each seed head, it rises up and drops off. As carrot seed requires two or three cuttings it is well to allow as long an interval between each as is safe, with the object of threshing the last of the seed at the time of gathering, cutting the entire mass of shoots at the ground instead of each individual head.

To determine when to gather the beet seed, crack between the teeth some of that which is green, and if the seed within cracks open white, the entire stalk is ready to cut. After cutting it may be laid on the ground until the outer shell, which contains the seed, is dry. Peas and beans, if left till fully ripe before the vines are pulled, may require a good deal of labor in picking over. Stack around a pole. roots in, having a barrel head or a few stones to keep the vines from the ground.—West Farmer and Dairyman.

General Agricultural Notes

HYDROLOGY OF SAN BERNARDINO VALLEY, CALIFORNIA.

The underground waters in the valley of the San Bernardino, California, where irrigation practice has attained a high degree of perfection, are of very great importance, as two-thirds of the irrigated acreage is dependent upon the underground waters, either wholly or in part. A report on the underground waters of this valley has been prepared by Mr. Walter C. Mendenhall of the United States Geological Survey, under the general direction of Mr. N. H. Darton. This report is now available as Water-Supply and Irrigation Paper No. 142, under the title of "The Hydrology of San Bernardino Valley, California."

The San Bernardino basin lies near the eastern end of the valley of southern California. When in 1851 the first band of Mormon immigrants dropped down through Cajon Pass into San Bernardino valley, after a journey of months across the parched deserts from Salt Lake, the abundant springs of pure water found in the valley must have appealed to them with a force which was greatly increased by the vivid memory of the loss of their companions by thirst in Death Valley but a short time before. It is not a matter of wonder that they decided that their wanderings should cease here and that they straightway began the building of homes, in which they hoped to spend the rest of their lives.

As early as 1810 a mission settlement had been affected at Politana and somewhat later another of more importance and greater permanence was established at old San Bernardino. It was there that the Mill Creek zanja, the oldest irrigation ditch in the valley, was constructed between 1820 and 1830. The first ditch of Mormon construction was not built until 1854. With this beginning, other small ditches were dug in the middle of the valley as the population increased. The irrigated areas were thus gradually extended, but large projects were not undertaken until work was begun upon the first Riverside canal in 1870. By 1876 both the upper and lower Riverside canals had been completed, and thereafter a constantly increasing acreage was brought under cultivation, until, in 1882, 4300 acres were supplied by these systems.

In 1883 the construction of the Bear Valley dam was begun, and with its completion, in 1884, the reclamation of the valuable citrus lands of the Redlands mesa was accomplished. In 1885 Matthew Gage undertook the construction of a higher canal, from which he proposed to irrigate a belt of the Riverside mesa lying entirely above the older Riverside canal systems. Unlike the other large canals of San Bernardino Valley, it has depended from the first chiefly upon developed underground waters, and the 7500 acres of splendid citrus lands which it has brought into the productive zone indicate the results that may be accomplished by the use of such waters. The final result of all these development schemes has been the reclamation of about 54,000 acres in the Redlands, San Bernardino, and Riverside quadrangles. Nearly all of this acreage depends upon the water supply from the San Bernardino mountains, either utilized directly as it flows from the canyons or recovered later from underground reservoirs.

The most important single element in bringing about this development has been the growth of the citrus industry since the foundation of the Riverside colony in 1870. Since the building of transcontinental railway lines which have given the fruit a wide market, the industry has grown rapidly and the need of irrigation has been greatly emphasized.

After discussing the rainfall, soils and water supply of the valley, Mr. Mendenhall describes the San Bernardino artesian area and other artesian wells in the Redlands and San Bernardino quadrangles. Those phases of the geology which throw light upon the amount, distribution, and movements of these waters are described by Mr. Mendenhall, and the effects of development and drought in bringing about those changes in water levels which have taken place in recent years are discussed.

This report is listed as Water Supply and Irrigation Paper No. 142, and may be obtained, free of charge, on application to the Director of the United States Geological Survey, Washington, D. C.

SOIL AND CULTIVATION FOR POTATOES.

The best potato soil is a sandy or gravelly loam which contains an abundance of vegetable matter, and which is well under-drained. In the best potato districts the soil will average about four feet deep. Below this is an immense layer of gravel which insures perfect drainage. Vegetable matter is secured by plowing under alfalfa sod. Alfalfa is grown two years, then turned under in the spring and planted to potatoes. Two crops of potatoes are grown in succession, then wheat is sown and the land again seeded to alfalfa, thus making a five-year rotation. The second crop of potatoes, however, is rarely as good as the first, probably because of the increase of fungus in the soil, and in most localities but one crop of potatoes should enter into the rotation system.

A heavy alkaline soil, that has poor under-drainage, furnishes an ideal condition for the growth of this plant disease, and it is in such soils that potato failures are most frequent. But poor under drainage in any soil is conducive to its growth. It will be seen, then, that cultivation and irrigation must be important factors in controlling disease. Most people who attempt to grow potatoes make the mistake of using more water than is necessary for the best growth of the plants. The rows should be comparatively short, so that part of the ground will not need to be over-watered. Frequent irrigation, using a small amount of water at a time, has been found by the writer to give best results. The seed should be planted about four inches deep in rows 38 to 40 inches apart. The furrows should be about five inches deep for the first irrigation, and with subsquent irrigations they should be increased in depth. The idea is to make the furrows deep enough to supply sufficient moisture to the roots without saturating the upper portion of the ridge, where the tubers form. Cultivation should follow as soon after as the ground is in condition to work The condition of the soil and plants should always govern the amount and the frequency that water is applied.

After all has been done in the way of culture, seed selection and a long rotation of crops, the vines and weeds should be collected and burned each season after the potatoes have been dug. This will destroy a great deal of the fungus that would infect other fields, as the vines are scattered by various means.—The Ranch.

FRUIT GROWING A VERY BROAD FIELD.

Do not think that because you have grown one successful crop of some particular fruit you know all that is necessary for the practical man to know about that fruit. Nor, when you pass an orchard in which an abundant crop is ripening with no one about save nature to make it grow, do not say to yourself, that because I can plant and reap I can make a success in fruit culture. True, it is, that splendid harvests are often had from fields that have received little from the hands of man. But such instances are like finding gold nuggets—you run on them incidentally; they form no premise for a working conclusion. No person can claim a right to expect success in the fruit business, or any other, for that matter, who depends solely on luck. One good crop does not mean success; it simply points to that possibility.

Fruit growing permits of a lifetime's study and observation of a kind that constantly becomes more and more interesting and profitable as the seasons go by. The mechanic deals with constant factors which after a time become monotonous, but the person who grows plants ever has the varied conditions of nature put together in innumerable forms, each of which produces its own results on plants, to manage.

One who has convinced himself that he will attempt to raise fruit must begin by deciding what kind of fruit will best suit his conditions and taste. Is this a small matter? Not if it is properly done. It means a study of the fruit of the community; an examination of the soil upon which the most productive kinds are grown and a comparison with the soil at the command of the investigator; a like observation of the surroundings as to lay of land, protection, etc., of the fruit. If the community does not afford examples for study, the task before the planter is more difficult to decide with certainty. Under such circumstances, he must inform himself regarding general conditions in which those fruits unknown in the neighborhood will prosper best, and judge if his conditions will suffice. As soon as the kind of fruit is chosen, other problems present themselves: What variety of the fruit will serve best? Where shall he secure his trees and bushes? When should they be planted? How pruned at planting time? How should the ground be prepared? At what depth will the trees or bushes do best? What about cultivation, cover crops, fertilizers, etc., during the years of development? Then, too, the insects and fungi troubles must be dealt with. The grower needs to learn these different enemies, the nature of their work, the treatment required to combat them.—Michigan Farmer.

"Why do you take the city census in July?" "We wait for the green apple season." "Why?" "Because much of our population in the suburbs will then be doubled up."—Cleveland Plain Dealer.

Farm Insurance.—Recent disclosures in the management of life insurance companies has led to discussion in regard to fire insurance as well. It is manifestly apparent that as much irregularity exists in regard to fire insurance as exists in life insurance. The system under which both are run is wrong. The expense of conducting the business of each is too great. The officers draw exorbitant salaries, some of them ridiculously high, so high indeed, as to leave little to meet the legitimate calls upon the corporations when losses occur. Fire insurance companies do not require expensive operation. In the country they do business comparatively cheap. Their losses are nominal and there is no excuse for the high rates charged by the board companies. We believe in insurance, every farmer should protect his property, in some company, but he doesn't wish, nor can he afford, to pay for his insurance a sum which is equal to the risk he can afford to take to carry his own insurance.

A State law could be framed, it seems to us, which would permit County Mutuals to extend their operations over territory beyond the counties in which they are organized, and allow them to do business in counties where no local companies exist. An insurance commissioner, whose duty it is to investigate the condition of the county mutuals, as is done in the case of State banks, should act as a check upon the operations of the companies and keep them safe and sound. The expense of mutual companies is not large about one-fourth to a half as much as the old line companies and the method of their operation simple. They can carry farm insurance, or at least they do, cheaper than the board companies, and the rule is that they pay their losses with less delay and more nearly to the amount insured.

The present system of farm insurance in this State is open to improvement. Some member of the State Legislature can do his constituents "a power of good" by formulating a law which will give to the farmer a cheaper, if not a safer means of fire protection. Of course, reliability in insurance is quite as necessary as cheapness, but it is possible to get both in a law which will protect the interest of the insured as well as allow insurance companies to make reasonable profits.

The ten mutual companies doing business in the State have insurance to the amount of seven millions of dollars, at an average cost of twenty cents per hundred per year—one-half of which has gone to pay for actual fires. The Insurance Advocate, of recent date, shows the cost of insurance between the stock and mutual companies of the New England States. That paper makes the declaration that:

"The average cost to the insured under these mutuals is 10 cents to every $100 written, which embraces losses and expenses; while in the stock companies the cost is, say, 90 cents to every $100 written. Therefore, in order to get down and run even with the mutuals, the stock companies must eliminate 80 cents from the cost."

"These mutuals possess the great advantage of virtually writing unlimited lines—take in the full value of the risk under one policy, and one scientific inspection, with which condition the stock companies cannot compete.

"The mutuals pay no dividends at a cost to the insured; while the average of annual dividends to the stockholders of a company is 10 per cent of the bare capital."

According to the Coast Review, the Board companies doing business in this State charge on the average, from one dollar to two dollars per hundred per year, for country insurance, about one-half of which goes to pay actual losses and the remainder to expenses. These rates, if correctly stated, debar the average farmer, and many townsmen, from the benefits of insurance, because he can not pay the price asked by the board companies. We are of the opinion that fire insurance methods along the plans of old line insurance need investigating and correcting fully as much as life insurance methods. Both systems are excessive in their rate of expenses. Their salaried officers and current expenses should be reduced to comport to actual business along commercial lines of the day.

* * *

About the State Fair.—The State Fair for 1905 is over. As usual, there is adverse criticism to the manner of its operation and to the methods employed by the managers in making awards. An exchange, in the central part of the State, takes the Cultivator to task for saying some complimentary things about the fair, this year, and characterizes the remarks made as the "same old rot in the same old way." The Cultivator has heretofore found it necessary to say some plain things about the management of the State Fair, because of the tendency shown to permit questionable shows and gambling devices to run on the grounds simply for the revenue derived therefrom. But this year the word went out that no concessions of this character would be granted and that the meeting should be in all respects clean and above criticism. We felt that it was the duty of the Cultivator to commend this determination of the managers and to urge the farmers to attend the fair and get all the pleasure and profit they could out of it. The State Fair is certainly a proposition that ought to appeal to the pride of all Californians. It is the farmers' exhibition of the year. It ought to be free from everything which has a tendency to detract from its influence or to lower its standard of excellence. That, of course, goes without saying. If gambling in races, or in anything else, is permitted, the management is at fault and it ought to be criticised.

There is one thing, however, which ought to be done by the people of the State, those we mean who support and control the fair. It has been demonstrated, we believe, very clearly, that there ought to be more than one place of holding the fair. Sacramento, the present location, it may be said truthfully, is too far away for the farmers south of the Tehachapi to send their hogs, cattle, sheep, horses and farm products. It is too expensive to ship these animals and products and takes too long to go and come. Then, too, Sacramento is not a large enough city to accommodate the people who attend the fair. One reason why the fair is not better patronized is the inability of the hotels to take care of the crowd. Then, too, there is the general criticism that exorbitant rates are charged for the occasion, by the hotels and that miserable accommodations are offered guests. This is a condition which calls for prompt correction. This is a graft which is too abomniable to tolerate. The State Fair would be twice as popular as it is were it made into two district fairs; one north of the Tehachapi, for the north part of the State, and the other south of the Tehachapi for Southern California. The territory is ample enough to support two great big fairs and if held on consecutive weeks exhibitions could be taken from one fair to the other, in most cases without material injury. A system of judicious advertising in the country and city papers would awaken an interest and add immensely to the patronage of the fairs. Spend some money in this direction, put reasonable prizes on animal and farm exhibitions and less on horse raising and the California district fairs will soon rival the far famed fairs of some of the Middle States. The present plan is behind the State's degree of progress, it's obsolete—and it ought to be changed before another year.

* * *

Will Not Resign.—The Secretary of Agriculture has written the editor of Successful Farming that he is not going to resign and the editor says, "because of this the people are glad."

There has never been an instant when there was the least suspicion of a logical cause why he should resign. In a letter to the paper referred to Mr. Wilson says, in reference to the report that he is soon to leave the cabinet:

"In a period of eight and one-half years while I have been endeavoring to build up a Department of Agriculture that would benefit the men who work in the fields with their coats off, I have been vigilant, and turned out nearly three hundred people who were misfits, or were leaning in the wrong direction, or were incompetent. And any wrongdoing now will be promptly punished. I am proud to say that all the glare of the lime light has been unable to show only one wicked man in six thousand, and that makes me very proud of my people here. They are a grand lot of men, the finest aggregation of scientists ever brought together to do work for the common people. To leave them now would be cowardice on my part. I must stand by them and fight their battles for them."

THE COLLEGE FARM.

Sacramento, Cal., Sept. 15th.

Editor California Cultivator: One of the principal topics of interest in the northern counties at the present time is the location of the agricultural farm, provided for by the last Legislature. There has been a very determined effort to locate it at Berkeley, whether or no, and this has aroused the farmers of both the Sacramento and San Joaquin valleys, in whose interest the bill was supposed to have been passed, and some very strong criticism is being indulged in in regard to the University and its connection with this matter. Even Prof. Bailey, who has a world-wide reputation as a horticultural teacher and writer, and who is generally respected where known, is coming in for no unstinted criticism as a "butter-in" in matters which could not concern him, and it is openly charged that he was imported from Cornell, at the expense of this State, in order to thwart the will of the people, as expressed at the last Legislature, and divert the money then appropriated from its legitimate channel into the University. It is to be regretted that a man so well known as Prof. Bailey should have allowed himself to be mixed up in a matter of local interest. It is a somewhat strange proceeding, too, that a man utterly unacquainted with Californian conditions, who knows nothing of our peculiarities of soil or climate, to whom irrigation is a mystery, whose whole education in his profession has been acquired under eastern conditions, should be brought to California to tell us what we should do. With all due respect to Prof. Bailey, it may be safely said that the opinion of some old California farmer on this matter is worth ten-fold more than his, and will probably have more weight with the commission. There is a very strong feeling growing against the present management of the University and this last act tends to increase this feeling. There is a constantly growing opinion that the University is absorbing too much of the government of the State, that it is reaching out for everything in sight, and feeling around for much that is not in sight, that it is departing from its original character as an educational institution, and endeavoring to become the governing body of the State. This course is gradually weaning its best friends from it and even Judge Shields, of Sacramento, who has always been one of the strongest friends of the University, made an address before the Live Stock Growers' Association, at the late State Fair, in which he denounced in no measured terms the effort to divert the agricultural farm appropriation to Berkeley, and in conclusion introduced a set of strongly worded resolutions denouncing such effort.

It is hardly to be expected that having made the effort to get the farm, that the University will give it up, but it now looks as though the opinion of the people who pay the money, will have some weight in the matter, and the commission will locate it in some farming section and away from University influence.—Agriculturist.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

B. F. Campbell of Orange, has a grove of Valencias which paid well this year. One tree alone paid $125. The tree is about thirty years old.

The almond crop in the Sacramento valley is now being shipped to eastern markets. The nuts are in fine condition and good prices are looked for.

In the country around San Martin and Gilroy the prune and peach crops are about all gathered and large shipments are being made from there daily.

Last week Wm. Calder of Orangevale, Placer county, received a bronze medal and diploma for his exhibit of oranges at the St. Louis Exposition last year.

O. L. Jordan, who has a ranch near Whittier, received a net return from two hundred and ninety Valencia orange trees this season of nearly $2700, or more than $9 per tree.

The district around Aromas, Santa Cruz county, is fast coming to the front as an apple growing section. Nearly two hundred carloads of fruit will be shipped from there this fall.

It is reported that two new canneries will be built at Marysville for the next year's crop, one by the California Fruit Canners' Association and the other by Rosenburg Bros. & Co.

A fruit item from the Mt. View Register says that at Niles, where fruit help was scarce this year, apricots were treated much the same as prunes. They were simply dried whole.

The wine grape crop in the Italian-Swiss colony at Asti will be about a two-thirds crop this year. The growers in that vicinity are receiving $16 and $18.50 a ton for their grapes.

A telegram dispatched from President Rossi, of the wine company of Santa Rosa, announces that only two-thirds of the normal grape crop will be produced in that section this year.

It is stated Rosenburg Bros. have drawn out of the fruit jobbers' combine at San Francisco and go independently hereafter. $25,000 is said to be the forfeit for the firm drawing out.

W. H. Schuyler brought to Santa Maria one day last week several hundred pounds of choice cherries. The cherries that are ripening at this time seem to be something like a second crop.

J. M. Laughlin, who has a fine vineyard near Windsor, Sonoma county, has on hand ten thousand Rupestris St. George cuttings and intends planting thirty acres more in improved wine grapes.

According to the Dinuba Advocate, raisin grapes in that vicinity are not turning out as well as in previous years. One place that yielded thirty tons last year only produced nine tons this year.

The Salway peach crop in the Santa Clara valley is being sold mostly to the canneries this year, though some are being dried. The dried Salways that were peeled are commanding seventeen cents per pound.

R. M. Dodge, fruit grower near Tulare, has discovered a new fig that he claims will stand shipping while fresh. The new fig is a reddish-purple in stripes of different shades. The flesh is rather dry but is very sweet.

John Q. A. Ballou, a farmer near San Jose, sold his peach crop this year, from an orchard of twenty acres, one hundred and twenty tons of peaches, at $47.50 per ton. Total cash received being $4750, or $275.50 per acre.

The annual report of the Upland Citrus association shows that six hundred and seventy-three cars have been shipped, the growers receiving $212,-931.19. The average paid for all grade navels was $1.19 1-7 per hundred pounds, or $.83 2-5 per packed box.

The yield of apples in the Pajaro valley is by far the heaviest of any in many years. Shipments are now being made from Watsonville at a rate of over one hundred and twenty carloads per week and should the present prices of apples prevail throughout the season the receipts will be enormous. Practically no damage is reported from the codling moth this season.

The olive crop in the San Fernando valley is turning out much better than at first expected. In the Los Angeles Olive Growers' tract it is estimated that fifteen hundred tons will be gathered and in the Pacoima and San Fernando sections about three thousand tons. About all of the old olives carried over have been sold. The season will commence about the middle of December.

Shipments of fresh deciduous fruits continue to be sent from Central California to the East in large quantities. Monday there were eighty-one cars sent out. Prices are holding up in an astonishing manner and growers are all making big money. A car from Florin sold in New York Monday for $1637, a car from Winters sold for $1228, and most cars sold over the $1000 limit.

The Marysville winery was destroyed by fire last Saturday, causing a loss of about $60,000. There was an insurance of about $32,500. The winery contained about 100,000 gallons of old wine, in addition to about 1000 tons of new grapes on hand. The loss to the winery is not only severe on its owner, but also to all the wine grape growers in that locality, as they will not have a home market for their product until the winery is rebuilt, which can not be done this year.

Happy Valley, in the vicinity of Olinda, Shasta Co., is elated over their success in gaining second prize for county exhibition at the State Fair, as it was their section which produced the fruit. Since many inquiries have been made for information regarding this section which produces such excellent fruit. The State analysis shows their fruit to contain from 3 to 4 per cent more sugar than any other section and the Cultivator man, who was recently through the valley, can vouch for the statement that it is good. The valley has plenty of water for irrigation and is an excellent berry country. Pears are fine and as yet free from blight, but growers are awake to the fact that vigilance must be exercised to keep it out. The grapes cannot be beaten for sweet juicy flavor.

AGRICULTURE.

The big sugar factory at Spreckels began its fall run this week.

A second fire in the Horst hop yards at Wheatland occasioned a loss of about $12,000. The kilns contained twenty thousand pounds of hops.

The Lompoc Record states that the potato crop in that valley is going to be very good this year. Indications being for a big yield of good quality.

For the most part the bean crop in Ventura county will be the best in years. In the Las Posas and Somis sections the beans were damaged, by the hot weather, from twenty to thirty per cent.

The 1905 crop of sugar beets in Ventura county is reported to be the best in its history. The average sugar content is running about 18.53 per cent. The campaign for the Oxnard factory is about one-half completed.

The Anaheim Gazette says that D. J. Mauerhan, of that place, is shipping one hundred and fifty crates of green chili peppers to Los Angeles weekly, where they are canned. The crop of chilis in that section is only about half what it was last year.

A. Fike, a farmer living near Laton, Fresno county, has by careful cross breeding and selection, produced a new type of onion. It is a cross between the Brown Globe and Silverskin varieties and is a large, white onion, very dense and has good keeping qualities.

A letter from the committee of agriculture of the State Board of Regents, signed by John E. Budd, Alden Anderson and Chester Rowell, states that the committee, after investigation, believes that the Tulare Experiment station is representative of the San Joaquin valley and should be continued. This station was recommended to be closed by Professor Wickson, acting dean of the University.

Hundreds of lima bean cutters are busy in Ventura county this week cutting the big lima bean crop. Threshing will begin in about two weeks, unless rain intervenes. There will be twelve threshing machines operated in the county and the biggest crop of limas in the history of the county will be harvested. Estimates vary as to the output, but there are predictions of from 550,000 to 750,000 bags. The crop will go beyond the 600,000-bag mark. The biggest crop on record so far is a half million bags. Many growers have contracted their crop at 3 cents.

LIVE STOCK.

The Raab Creamery Co. is having the plant at Monrovia repaired and will start it in operation again shortly.

An effort is being made to organize a cattle breeders' association for Central California, with headquarters at Sacramento.

Geo. Whitlock has sold his dairy ranch near San Jacinto to J. A. McNulty of New York. The new owner plans to run a first class dairy.

C. E. Gunther, of Ethanac, reports selling the milk from eighteen dairy cows to the Arlington Creamery and receiving an average of $150 per month.

A fire that desrtoyed over $50,000 of feed on stock ranges and burned over 15,000 acres of land, occurred near the Sutter Buttes in Sutter county, Monday night.

Shipments of fat mountain cattle have commenced from Red Bluff. Most of the cattle are sent to the San Francisco market and some are being sent to Mississippi points as an experiment.

The regular quarterly meeting of the State Veterinary Association was held at Berkeley last week. Officers were nominated for the coming year and will be elected at the next quarterly meeting in December. About forty members were present.

The Brawley News, in its last issue, gives an account of how one man made some money on hogs in the Imperial valley last year. A. L. Hamilton bought $900 worth of hogs about a year ago. He sold $2000 worth after fattening and is now ready to make another large shipment.

Dr. Chas. Keane, State Veterinary, has been conducting a number of experiments in injecting into the animal the culture of human tubercle bacilli, by which he hopes to render animals immune from tuberculosis. Samples of the necessary culture have been received by Dr. Keane from Germany.

The greatest live stock show ever held on the Coast opened Tuesday at the Lewis and Clark Exposition, at Portland. Stockmen from all over the country made entries. The show will continue for ten days, closing on 29th of September. Premiums aggregating $50,000 have been offered by the management.

In spite of the fact that supervisors of Tulare county turned down the appropriation of $1000 for a stock exhibit at the fair in that county this fall, the directors have decided, upon the request of one hundred and eighty-six stockholders, to have a stock exhibit at the time of the fair. No premiums will be given but it is believed that a fine display of stock will be made.

The annual meeting of the Solano County Sheepmen's Association was held at Suisun, Monday. This association was organized about a year and a half ago by the leading sheep owners of the county for the purpose of providing means of protecting sheep from the ravages of coyotes. The sum of $20 is paid for each coyote scalp. Since its organization the association has paid for fifty-one such scalps.

MISCELLANEOUS.

The great Chino ranch, consisting of 38,000 acres, was sold at auction by the sheriff at Los Angeles, Monday, to quiet title. The Chino Land and Water Company now owns clear 14,000 acres of the land, valued at $2,000,000. It is announced that the company will subdivide a large part of their holdings and sell in ten acre lots.

In the hope of getting some deadly bacterial disease to spread among the grasshopper swarms throughout the State the entomologists of the University of California Agricultural Experiment Station are now studying the pathology of a peculiar plague which has just been reported among the hoppers at Los Banos. At that locality the insects died in great quantities when stricken with the new disease, and when the malady was crudely spread throughout a whole ranch the insect horde was practically wiped out of existence. The insect experts of Berkeley expect to find out the nature of this disease and get it under such control that it can be transmitted to other swarms.

C. H. SESSIONS, ASSOCIATE EDITOR

FEEDING THE HORSE.

From an address made by Dr. H. A. Spencer before northern farmers' institutes some time ago, we quote the following extracts. In speaking of the importance of well cared for teeth the doctor calls for more intelligent veterinary study of that department of the veterinary science. On that point he says:

"In no branch of veterinary science it it more important to possess an accurate knowledge of the conditions which are present in a state of health, as well as disease, than in the care and treatment of the teeth. It is only by a thorough knowledge of the appearance of an organ during health that we are enabled to distinguish any deviation from that condition.

"Horses of all ages suffer more or less from long, sharp and projecting points which are found on the molar teeth. They are located on the inside of the lower and outside of the upper grinders, and occasionally also on the inside of the upper ones; they vary in size and shape, some being small and blunt, while others are long, thin and very sharp. The injuries they inflict are lacerations of the cheeks and tongue, and a limitation of the lateral motion of the jaws; unless this motion is extensive enough to permit the whole crown of the tooth to come in contact with the food to be ground, much of it will not be reduced to a proper consistency. Other difficulties also arise, such as decay, ulceration and malformation.

"As well set a hod carrier to mend a piano or a typewriter as to expect a person unfamiliar with anatomy and physiology to correct the irregularities of so delicate a structure as the mouth

* * *

"How to feed! A horse should be fed with reference to what he is to do. The horse doing slow, but hard and exhausting labor, should be generously fed on grain three times a day, with as much clean sweet hay at night as he will entirely consume, bearing in mind that the hay in this country, unlike the grass product of the prairie States, is rich in grain, therefore much more nutritious, and a less quantity is requisite to satisfy a natural appetite. There is an inclination on the part of most horse owners and hired help to feed vastly more hay than is required, under the mistaken idea that they are being generous to the stock, but horses, if permitted to do so, will develop abnormal appetites, besides often wasting more than they will consume. We have seen that the stomach of that animal is relatively smaller than that of most other animals; this being the case, it is obvious that if permitted, the horse will, even after filling it to repletion, and distending it to an extent that materially limits muscular contraction, continue to force more into it, thus compelling the pyloric orifice to open for the passage of aliment only partially prepared for future adaptation and final assimilation. In addition to this, the distention of the stomach limits by pressure the action of the lungs, thereby curtailing a proper amount of oxygen being absorbed for the clarification of the blood, besides causes a retention of poisonous carbonic acid gas in the system. Neither should a horse be permitted to drink immediately after feeding, as by this course the stomach is filled with a fluid that dilutes the saliva, gastric and other digestive fluids, and washes the contents of the stomach into the intestines, producing looseness and scouring; while on the contrary, if compelled to partake of water before feeding, he has no abnormal thirst and takes only such quantities as is necessary to give proper fluidity to the tissues of the body.

"Under the subject of hay we have in this county four principal varieties, viz: Wheat, barley, oat and alfalfa. Of these I am constrained to believe that the former, if well cured and clean, is by far the most suitable for horses used exclusively for draft purposes. It is rich in fat producing qualities, and, while succulent and wholesome if cured carefully, and not too green, seems to assimilate nicely, but the consumption of it by driving horses does not seem fruitful of a condition of fitness for road purposes, as does that of either oat or barley hay. Oat hay of good character appears to be the most satisfactory provender we possess for road horses; the chief objections to barley hay is the annoyance that the beards produce in making the mouth sore, and that it is so rich in fibrin producing elements that some individuals become afflicted with skin affections which prove very refractory and troublesome. Alfalfa hay, I think, is of more value for brood mares, colts and unused horses, than for other purposes. It has good milk and fat producing qualities.

"Economy sometimes dictates a carefulness akin to stinginess in feeding. In cases where one's finances compel extreme caution, it were best to expend what money we have to spare for the best products we can procure, and then cut and moisten the hay, which by the addition of a little bran and middlings well stirred, makes a cheap, effective food, a measurably small quantity of which, fed fresh and unfermented, makes strength and satisfies the appetite; but some uncut hay should be used in conjunction, however, very materially less than if the cut mass had not been administered. By this mode of procedure, from one-third to one-fourth of the ordinary expenses of the "keep" of animals may be saved, and their health remain unimpaired.

"Of grain I should say that for driving horses oats are by far the most satisfactory. They seem to have the needed material for bone and muscle building, and do not produce excessive fat, which, in a gentleman's driver, renders him logy, dispirited and easy to fatigue.

"Barley is admissible in the winter months where fat and its consequent warmth is desirable, but under any circumstances during enforced idleness and over Sunday, both hay and grain should be materially reduced. In fact, it were better if the latter were taken away entirely, and a well made mash of bran substituted.

"By observing these last instructions you will undoubtedly save your horses from many an attack of colic, azoturia, lymphangitis and other complications that are frequently fatal, and always call for the expense attending the visit of a veterinarian, to say nothing of the drugs and nostrums you may administer.

"It becomes more manifest to me every year that we feed our stock more hay than they require to keep them in a condition of health and fettle commensurate with their comfort and our requirements, and while it is impossible to lay down any rule that will apply collectively to the horse family, I am led to believe that the ordinary horse that consumes more than fifteen pounds of hay, at either one or at two meals in twenty-four hours, is eating and destroying more than is good for either him or his owner.

"An important feature in the conditioning of horses is grooming and sanitation. One familiar with the difference in the keep of a well-groomed, warmly housed animal, and one that has an over sufficiency of food, but is forced to inhabit an ill-smelling, cold stable, and whose coat

Sharples TUBULAR CREAM SEPARATORS

21 POUNDS MORE BUTTER PER WEEK

Barnesville, Ohio, June 20, 1905: We were milking ten cows May 19. That day we took a Tubular separator for trial. **We used it one week and got 86 pounds of butter that week. The week before** we used it, we got only 65 pounds. **The week after** the agent took it away we got only 64 pounds. We felt we ought to have it. Later we arranged to buy it. We recommend the Tubular to anyone interested in cows. It surely will pay any one to buy a Tubular.

receives no attention, would be astonished at the difference. We often find horses running to a straw stack, and perhaps a load of carrots or squash is piled up for them. Now, whenever we find these conditions we find a large percentage of the stock afflicted with worms, and the reason is palpable. An insufficiency of proper nutrition vitiates the alimentary tract, and the parasites invade it, for these parasites cannot exist in a perfectly toned digestive tract, while they revel in a disordered one. I do not wish to detract from the value of a few carrots fed ocacsionally to add zest and relish to the stomach, but partaken of as a regular diet I believe them to be pernicious. The matter of economy then resolves itself down to the proposition that we should have only such a number of horses as will properly perform our labor and we can properly care for."

STUDY CONSEQUENCES.

Fifty years or more ago, when a lad working by the month for an old farmer who was a born teacher, we did a piece of corn hoeing in a careless, indifferent way. The old man called our attention to the work and said:

"You hoed that corn with your mind not on your work. You must make a mind study of what you are doing. Always when you are working study the consequences of what you are doing and the way you do it. If you get into that mental habit you will see results loom up ahead of you and you will never work hard for poor results as you did when you hoed that corn."

That was a most valuable lecture to us. It opened a new idea of work. We could see as we studied it that every turn of the hoe was fraught with consequences good or ill to the corn.

A great deal of the work men do on the dairy farm is done without any study of consequences. It is a great gift to be able to foresee the consequences of our acts.

Not long since a neighbor applied to us for advice about his alfalfa. A year ago we advised him to test his seed, but he "hadn't time," he said. A year has been wasted, and all his labor, and only a few spears of alfalfa are shown. It would have taken him possibly a half hour to test the seed. We tested some of the seed he had left over, and one in twenty would grow. He did not study consequences.

Last fall we urged a farmer to build him a well constructed calf stable where he could surround his calves all winter with right conditions for calf growth and development. He turned up his nose in disdain at such ideas; said he knew how to raise calves and all that. He happened to be at the depot when we were shipping a bunch of grade Guernsey heifer calves between six and seven months old. He admired the thrifty appearance of the youngsters and admitted that he had never produced such calves himself. It seemed to jar him when we told him that one great reason for their growth was the warm, well constructed stable they were reared in. These calves sold for $20 each; his calves could be bought easily for $10 to $12 apiece.

Here was a good chance to study consequences. "And so goes the game of consequences to an almost infinite degree."—Hoard's Dairyman.

SILAGE FOR CALVES.

Speaking of the best food for calves, the Jersey Bulletin says:

As a feed for young and growing calves, silage can be used to great advantage. Its succulent properties keep the youngster in a sappy condition which is so essential to rapid growth and development. Its laxative effect upon the digestive tract aids digestion and keeps the calf in a healthful condition. To distend the barrel and increase the capacity of the animal is one of the essential points to look for in feeding the calf, and in this silage has no equal as a winter feed.

Although I know of no actual experiments having ever been performed to ascertain if silage may be fed too heavily for the best results, I am of the opinion that it is often so fed, owing to its bulky nature and lack of dry matter. When fed too heavily the animal can not eat enough other foods, and thus lacks a source of feeding nutrients from which to derive a sufficient amount of nourishment to produce the best results either in milk production or growth. It is a question whether it should be fed in greater amounts than 40 pounds per thousand pounds live weight of the dairy cow.

CAUTIONS TO DAIRYMEN.

Never let the heifer become more than three years old before breeding. Cows which have been bred young are usually good milkers.

Milk set in shallow vessels is more liable to sour than that in deeper ones.

It is never advisable to wash the butter too dry, but avoid leaving too much water in it, as it is then more liable to spoil. A good rule is to have dry butter for storage, and fairly moist butter for immediate use.

Keep the fresh, warm milk separate from the old. It keeps better.

Test your milk. It is not quantity so much as the quality that counts.

If you are buying new milk utensils, see that all points are smoothly soldered.

Soft, white butter comes from hot cream.

Too much sourness in cream causes white specks in butter.

Set milk after milking before it becomes as cool as the atmosphere. The cream will rise better.

Have the milk for the calves sweet and of the same temperature as when it comes from the cow.

Keep the heifer, intended for the dairy, in thrifty, growing condition.

Milk quietly, cleanly, quickly. Cows hate haste.—Montreal Star.

LICE AND MANGE.

Ordinarily hogs are not affected with trouble from lice or mange as much as one might believe. It is a fact, however, that many hogs are affected that are not believed to be. When lice get on the old ones the little pigs are sure to get them later on and trouble will surely result. Little pigs when thus irritated by the biting of the lice are sure to rub against walls and fences in their efforts to get rid of the pest. Their energy is thus utilized and they never have perfect rest. The result is that they cannot grow properly and usually become stunted. Mange is very similar in effect. The hog, in addition, develops a very thick skin and when once developed it seems very much like the shell of a mud turtle. It will not yield, and the pig, apparently, cannot grow, no matter how fed. Now hogs do not seem to develop mange so freely nor breed lice in such great numbers when in an open pasture, and in free access to a mud wallow, but even then these irritants thrive sometimes.

The only way to have complete freedom is to clean up the hogs. This can be done by washing or dipping with a dip that kills these parasites. One of the best methods to follow where the above is not practical is to build a shallow cement or wood tank, say a foot deep, filled with a dip for about four inches. When placed in the hog yard, the pigs take great delight in wallowing in it and in that way are kept clean.

ADVANTAGES OF SILAGE.

The digestive organs of animals that chew the cud are so formed as to require comparatively juicy and bulky food. The cow cannot, therefore, thrive on exclusively dry food so well as can the horse. The nearest an ideal food that can be obtained for the dairy cow is good pasture, but where for more than six months in the year green pasture is not available the best substitutes to use during this period are corn silage and such roots as mangels and turnips. Corn yields an average of twice as much dry matter per acre as do root crops.

BEEF SCRAPS FOR POULTRY.

Mr. S. H. Church informs us that the Swift's beef scraps and blood flour are proving invaluable as feather and as egg producers at this season of the year. The third car for the past few weeks is now on the road. The growing use of these products is proof of their appreciation by poultry and stock growers. By the way, the blood flour has been found most advantageous feed for young calves and pigs. Pigs grow like weeds when given a small ration of blood flour with their other ration. It is sold in small quantities at 5 cents per pound.

POSITION AS FOREMAN

Young married man, capable of taking position as foreman, assistant or entire supervision of ranch, wishes situation. Citrus or alfalfa preferred. No children, but will want house. Can give best of references. Write, giving wages, to H. J. L., Box 1B9, Alhambra, Cal.

A Profitable Poultry Ranch

FOR SALE

H. H. Holland, Fresno, Cal , offers the El Oro Poultry Farm, of about five acres, one mile from city limits and one-half mile from electric car line. About 400 mature fowls and 500 young ones, from best strains of birds. A home, a good living, and a margin of $500 to $1500 per year. One-third cash down, balance long time.

Place has growing alfalfa in every yard and several hundred fruit and shade trees. Entire place enclosed in 8-foot wire fence and divided into about 20 yards. I have 4000-gallon water tank, 6-horse-power gas engine, 2 100-foot wells, 4-inch centrifugal pump, brooder house, 2 large brooders, 2 large incubators, incubator cellar, water piped to every yard, 2-story barn, buggy sheds and outbuildings, garden tools, windmill and pump, 8-room house, acetyline gas plant, solar heater.

My reason for selling is want of sufficient time to devote to the business. Address

H. H. Holland, Fresno, Cal.

When writing advertisers mention Cultivator.

Queries and Suggestions

BOARD MEASURE.

Mr. A. B. Gibson, of Ukiah, sends solution of problem of board measure of log 100 feet long and two feet diameter at both ends. The answer which we gave was 2525 feet of merchantable lumber, possible to secure. It seems the question contemplated the entire measure, with no allowance for saw cut nor trimming up of edges, etc. In that case the following is correct. Of course it is not possible to saw out twelve feet of lumber from a cubic foot, though it is actually there before sawing. Mr. Gibson's solution is:

Solution.—A foot of lumber is taken to be one foot square and one inch thick. Therefore: A cubic foot will contain twelve feet of lumber. Therefore: 2 squared x .7854x100x12 equals 3769.92. Therefore: The log contains 3769.92 feet of lumber.

MUDDY WATER.

Editor Cultivator: I bored a well on my place but I find that the water continues to be muddy. Will you tell me how I may get the sand and gravel out of it? The sand is a coarse red material and will not separate from the water easily. I am going to try running it through gravel, but would like your view on same.—A. B. Gibson, Ukiah.

You probably have struck a vein of quicksand and we do not know of any remedy for such a condition, for there is nothing which would prevent the sand from flowing into the well.

BROME GRASS.

A subscriber wishes information regarding the advisability of planting in California the Hungarian Brome grass (Bromus Imermis).

Regarding this, the report on Grasses and Forage Plants, by Professor Wickson, of the State University, says: "This grass was introduced by this station from Europe. The drought-resisting character of the grass was early seen in our experimental plots in Berkeley; and, grown alongside of Schrader's brome grass, has surpassed it in satisfactory growth, being softer and more leafy, and bearing seed which clings more tenaciously to the stems, which are finer than those of Schrader's brome. Under the conditions prevailing in the central coast region of the State, it may be commended as likely to please the grower better than Schrader's. The seed has been widely distributed throughout the West during the last two years by the United States Department of Agriculture, and is now to be had from seedsmen as well. It is worthy of the widest trial."

The United States Department, in Bulletin 12, speaking of stock ranges in northwestern California, says: "Awnless brome grass, though a native of Europe, was introduced into California from New Zealand about the year 1880 by the Agricultural Experiment Station of the University of California. It is a perennial with stout, creeping rootstocks and stems two to five feet high, and is useful both for pasture and meadow. It is a good winter grower. Its nutritive value is comparatively low, but it is well worth trial on the poorer sandy soils along the coast, as it is one of the most promising grasses for such situations. It is unusually resistant of drought, and when once established is somewhat difficult to eradicate. If sown alone, about three bushels is recommended."

However, we note in Bulletin 59, by the Department, that, grown up in the North and Western States, it gives fair results, yet in Southern States it is not satisfactory. This may possibly mean that in Southern California it would not do so well as it may in the Northwest. However, we ask subscribers who have had experience to inform us of its adaptability to Coast conditions.

LEAKING PIPE.

Editor Cultivator: A company of your readers here had a cement pipe put in about a year ago, and it does not hold water as well as it should. Too porous, it was not washed with c
Is there anything you know of that could be thrown in the water and run through that would stop the leakage? What effect would bran have on it?—S. F. and P., Redlands.

We do not think that bran would have any permanent effect on stopping leak though it does work, of course, in the case of casks or barrels, to stop the immediate leak until they can swell up as a result of soaking of the water. It will probably be impossible to get the best results out of such a pipe and it is, indeed, unfortunate that it was ever put in without being washed inside with a solution of pure cement. If the pipe is fairly straight and not too long, it is barely possible that a stout cord or wire could be floated through and attached to a bunch of sacks, or other "plug," at the lower end. Then, when the water is all out, by flooding in a solution of cement and water sufficient to fairly fill the pipe at lower end, then drawing the "plug" back, the wash might fill the pores of the pipe so as to prevent future leaks.

SUGAR BEETS AND TOBACCO.

Editor Cultivator: Kindly inform me whether sugar beets will grow during winter and variety most profitable. If not profitable for winter growth, what time in the spring is best? What are the prices per ton and can beets be sold to the sugar factory direct?

Can tobacco be raised with profit in this section?

Please tell me reliable chemist to analyze soil.—Newcomer, Petaluma.

We do not think that sugar beet growing will be attractive in your section as there is no factory near at hand to take the product. In any case, they are not planted during the fall for the purpose of sugar manufacture, though the subsoiling and preparation of the ground often begins during the fall season. Seed planting is several months later. The sale of the beets is made direct to the factory, though usually under contract signed the year before for the season to come, so that when the seed is planted the farmer knows exactly the place of marketing and the price per ton. The price per ton may be $3 or it may be $5, depending upon the sugar content of the beets, distance to ship, etc. The sugar content is largely estimated by the adaptability of the soil, which is usually determined by testing during a period of several years. If you wish beets for stock purposes, you plant almost any time, so your ground is in moist, well-tilled condition. For this purpose, the mangel, or a larger and coarser growing beet will give more than twice as much tonnage as the sugar beet, which is a comparatively small beet.

Regarding tobacco culture in your section, we question whether it will be a commercial success, though it has been grown experimentally in all sections of California and in some places efforts have been made to manufacture in a large way, but this, we believe, has generally been discontinued.

Regarding soil analysis, write the State University, Berkeley, California, and complete instructions will be sent.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

PREVENTION OF ROUP.

"One ounce of prevention is better than a pound of cure," is a wise old proverb that applies to all poultry diseases, but more especially to the dread disease of roup.

I am sorry to say I have already had several letters from poultry raisers telling of a visitation of roup amongst their turkeys or half grown chickens, and asking for advice. Some of the letters end with "please send me a remedy and tell me what caused the disease?" I try to answer these conundrums to the best of my ability, but I wonder how a doctor would reply were he to find a letter in his mail saying. "I have the grippe; please tell what gave it to me and send a remedy."

In my talks on summer work in the poultry yard I have had in view not only getting through the moult in good shape and quickly, but also the elimination of roup and kindred diseases and the building up of a flock of vigorous, healthy fowls, able to withstand sickness and ready to fill the egg-basket in the fall and winter.

Roup is very much like grippe (influenza) in the human family. It is a very infectious disease. It is met at every season of the year, but is more common in the early fall and winter, especially amongst fowls that have been neglected. A hen in the early fall is in an anaemic condition, she is moulting after a long season of laying, a moulting hen is only half clad, is ready to take cold or have indigestion or bowel trouble at the slightest provocation. A hen afflicted with lice is in a still worse plight and if the proper food and care have not been given, she is apt to fall a victim to the first microbe of roup that presents itself.

You all know my recipe for getting eggs: "Comfort, exercise and proper food." These are the three conditions of egg production. The first prevention of roup is "comfort," and the first item of comfort is cleanliness. Fowls with roup almost invariably have lice and the henneries are infested with lice, mites, fleas, etc. The lice carry the roup microbe from one fowl to another. Some scientists say that even flies and fleas carry the infection. I know that the lice go to the fowls' eyes to drink and in that way they can carry the microbe, with the infection, so that one fowl with roup and lice may infect the whole flock.

The first prevention of roup is to get rid of all lice, mites, fleas, for your pocketbook's sake as well as for the comfort of your fowls. The second prevention is freedom from draughts. The fowls' roosting place should have plenty of pure, fresh air, but no draughts. I lost a beautiful cock bird, a first prize winner, years ago, from a hole only as big as a thimble. It was at a time when this part of the country was infested by chicken thieves. Two men, one dark night, got over my back fence and drilled the little hole in one hennery, intending to saw out a panel, our dogs heard and attacked them and the neighbors saw the men running away. That little hole caused the death of my beautiful bird.

A draught of air in this part of the country will give a person neuralgia. It will give practically the same to a hen; cold, and swell-head. Roup commences often from a draught, and the smaller the draught the greater the danger, for it cuts like a knife.

One hot summer the boards in one of my new henneries shrank and unknown to me there were cracks between the boards. An expert poultry man was visiting me. "Several of your cockerels have slight colds," said he; "there must be a draught in their roosting house." And in he went, down on his knees in the hennery. "Come and look for yourself," he called, and I did. I crawled round on my knees, putting my head on a level with the perches, found every crack and knot hole and nailed a lath over each. I gave the cockerels a little tonic and some bluestone in the water, and in two days they were well. If I had neglected these little cracks I might have had a visitation of roup and pronounced the poultry business a failure.

Another prevention is proper ventilation of the houses. I am rather a crank on ventilation. I sleep with my bedroom windows open always and I want my henneries certainly as well ventilated. The "mushroom" houses, which are houses with bottom ventilation, open for six or eight inches all the way round the bottom are good, or houses with one side entirely open (that side away from the night breeze) or a house made of burlap, or of common domestic muslin will have proper ventilation, yet shelter from the night breeze and protect the fowls from fog or dew or rain. Of course, I am speaking of the Pacific Coast climate, especially that of Southern California. Back East the poultry books give directions for double walls lined with paper and stuffed with straw. Here we do not have zero weather to contend with and muslin or burlap is shelter enough.

Another prevention of roup is plenty of succulent green food. An abundance of green food will give immunity from roup. Green food is by far the cheapest food you can give the fowls and keeps them healthy. A well balanced ration will eliminate sickness and in a well balanced ration there must be an ample supply of green food.

Another prevention is clean water. Water is even cheaper than green food, and yet it is astonishing how careless some people are about supplying it. Water is one of the chief carriers of roup. Each yard should be supplied with a separate drinking vessel. I know a gentleman who was ruined by letting the water run through his yards. He had a fine ranch, and kept a small stream of water running all the time through his yards. The ground sloped gently so the water ran down hill through the troughs, one after another. He bought fifty fine young pullets, perfectly healthy he thought, put them into the yard, and within a week his whole flock was af-

fected with a virulent outbreak of roup. The new pullets had roup, drank from the running water, and, he said every yard was affected and he failed in the poultry business in consequence.

Carelessness in the management of fowls is the usual cause of illness. Next week I will give a number of cures for roup, although "an ounce of prevention is better than a pound of cure."

* * *

EDITOR'S QUESTION BOX.

I am sorry to say that I have lost a letter signed "Grace Jones," and cannot remember the contents. Will the writer give me her address and let me know what it was that she wanted?

* * *

Time of Setting Indian Runners.—(N. E. M., Santa Ana.) If Indian Runner ducks do not lay during September and October, then it is not profitable to set the eggs before April 1st. Is that right?

Answer.—Indian Runner ducks' usual resting time from laying is in October, but young ducks begin to lay at about five months of age, if properly fed, and by judicious hatching in the spring, the young will be laying whilst the old are resting.

* * *

GOLDEN WYANDOTTES—ROCKS.

Editor Cultivator: Will you kindly answer through your paper: How does the Golden Wyandotte compare in size with the Rocks? Where could one get a setting of eggs from the Golden Wyandotte?—J. D. Black, Redlands.

Answer.—The Wyandottes are one pound lighter in weight, according to the Standard than Plymouth Rocks. 2. I do not know, as there are none among our advertisers.

CURING THE GAPES.

I keep wheat soaking in a small bottle of turpentine. If a chick wheezes, snuffles and rattles as though it had a cold, this is the forerunner of gapes. When gapes are unusually violent and fatal a chick may begin gaping without showing these. In such case the chick is nearly always a goner. Carbolic acid will help him if anything will.

Pour a little refined carbolic acid in a spoon, hold it over a lamp, and dense, white fumes will soon arise. Hold the chick's head in these, drawing him away for a second or two to let him catch his breath. Don't let him get his bill in the acid. If you look at the acid in the spoon before you pour it back in the bottle you can often see the tiny red worms that the fumes made the chick cough up. Five cents' worth of acid will doctor dozens of chicks. If the chick is only coughing, two or three grains of the wheat or a tiny piece of assafetida may cure him. If he is still wheezing the next day repeat the dose. I never failed to kill a chick that I gave both carbolic acid and turpentine in one day.—American Agriculturist.

VALUE OF THE INCUBATOR.

The incubator is a great machine and the few poultry raisers who do not own one now will at some time in the future. The machine is a better money-maker than the hen. The incubator will not be driven from the nest by mites and lice; it won't get contrary and decline to set; it doesn't get foolish and smash the eggs, smearing the nest so that the unbroken eggs won't hatch, and it does not sit long enough to hatch one chick out of twenty and go off with it, forgetting to come back to hatch the rest. —Farm Magazine.

THE TAIL TELLS A TALE.

There seems to be a significant relation between the tail and the body type of some of our animals. The dairy animal has a long tail with heavy brush, while the tail of a beef animal is short and almost without brush.

The race horse has a long, heavy tail, but the draft horse has a stubby tail with very scant covering.

The egg type hen has a big tail and the meat type hen has practically no tail.

I never had opportunity to measure the tails of bacon and pork hogs to see if they averaged any different.

Anyone can observe the differences I have cited. Who can account for it? —Kimball's Farmer.

TO KILL MITES.

To kill the mites mix air slaked lime and kerosene oil and put on roosts with a brush.

If you want your chickens to be up to weight at show-time, if you want them to have large, blocky frames that will hold lots of meat and fat, feed them green food every day of their lives after they are two weeks old. This presupposes that you also feed them sound, wholesome grain every day, with occasionally a feed of fresh cut bone or meat.

The flavor of hens' eggs is declared by an English medical man to be very materially affected by food. When the hens act as scavengers their eggs are made unfit to eat, but a diet of sun flower seeds produces remarkably fine and sweet eggs.

If a hen lays three eggs a week she will give double the profit derived from a hen that lays two eggs. The greater the number of eggs the cheaper the cost of production in proportion.

With poultry for fattening purposes solely, grain should be fed almost exclusively and the mere fattening process should not take more than ten days or two weeks, for poultry, or in fact, any kind of meat, fattened quickly, is much more juicy, tender and appetizing than that which has been fattened slowly.

Be careful in adding extra fowls to the flock as it is quite difficult to detect diseases without a close examination.

When beginning to raise capons, get a set of instruments and practice on dead fowls. In a short time you will be able to operate on live ones. For capons raise only the larger breeds.

Don't let the young poultry shift for themselves. Keep them growing through the summer and fall. Provide perches for the chicks, don't let them sit in piles at night.

The cheapest and best of all feeds for poultry is sunflower seeds. Egg production always increases as soon as sunflower seeds begin to mature. They are not fat producing, like corn, hence laying hens can have free access to them.

Send your poultry to roost with a full crop.

CULLINGS.

Generally, when the time for culling young stock comes, the experienced breeder has a great advantage over the beginner. The former can tell at an earlier date the birds that will be profitable to keep over; the latter must learn by experience.

If there be anything to hinder your charring wood and breaking it in pieces about the size of a grain of corn or smaller, parch the grain occasionally.

Don't feed tonics even during moulting time. They stimulate for a time but do no real good.

Give a mash consisting principally of cracked corn with plenty of cool water, shade and whole corn.

If there is danger of prowling animals provide screens of poultry netting for both doors and windows.

Sunflower seed is among the most valuable of all the moulting foods. Fed even in very small quantities it is of great assistance in producing new plumage and aids the dropping of the old.

Do not allow the young chickens to crowd in their sleeping quarters at this time of year. They very soon outgrow the brood coop and should have roomy quarters with wide flat roosts. Crowding now is laying the foundation for colds and roup.

If you are crowded for space but still desire to keep chickens, try bantams. They stand confinement as well as canary birds and pay as well in proportion to the expense of keeping as any of the larger fowls. There are enough different varieties of fowl to suit any taste.

Throw some river sand or gravel in a sunny corner of the chicken park. The poultry will enjoy a good sunning and a dust bath.

For constipation in your flock give a sprinkle of red pepper in the food. When the bowels are loose use black pepper. Keep plenty of clean water where the poultry can get at it all hours of the day.

Give the poultry a pan of buttermilk or thick skim milk occasionally.

CONSISTENT COWS—ALFALFA PASTURE.

Our cows are so consistent that after it is written once it is merely a matter of repeating. So far as feed is concerned, the one word "alfalfa" covers the entire ground, as we never grain after the first of April. Our cows run on the alfalfa pasture both day and night, and get some alfalfa hay morning and evening, as soon as we finish milking. I suppose most of the eastern dairymen would have an attack of heart failure if their cows were to get into a field of alfalfa two feet high; but we turn our cows into such feed. By the way, tomorrow morning the fourth cutting of alfalfa will begin to fall. How is that for a feed-producing country?—J. G. Stahl, Bakersfield, in Jersey Bulletin.

"THE AGE LIMIT" FOR DAIRY COWS.

The Montreal Star says: "After a cow passes much beyond nine years of age, she begins to deteriorate." This is not always the case, and it depends on the breed, too. Dairy-made cows don't stop at nine. Many good cows go to fifteen and then some, if properly treated.—Jersey Bulletin.

TURPENTINE FOR SWOLLEN UDDER.

A writer in Hoard's says: I use turpentine for swollen udders. If applied as soon as discovered, will reduce all inflammation inside of twelve hours and save it perfectly. Fill the hand and bathe part or whole udder as it happens to be, and if the cow is cold apply to ears, back of head and whole length of back. In bad case, also to stifles if swollen. It will reduce it in twenty-four hours, and is a great deal better than any liniment to be had.

I use it also for bruises on human flesh, especially prick with nails.

Apply to bottom of horse's feet for soreness, stone bruises and hard hoofs. I use also salt and water for dry hoofs, but never put any kind of grease on horse's hoofs.

MAKING OF CHEESE.

For the production of large quantities of cheese of uniform excellence it is believed the American factory system, common to the United States and Canada, is superior to anything elsewhere, and more systematically and economically conducted. The average Cheddar cheese of the Cheddar valley itself, of Somersetshire in general, and of the best producing districts of England and Scotland, are no better than those of New York and Wisconsin and the best of Canada. In variety and fancy cheese this continent can not yet attempt to compete with the old world.

COW POX.

In cow pox and diseases of the udder that are sometimes mistaken for it, the proper precautions should be used in order to prevent the milkers from spreading them. After milking a cow, the milker should wash his hands in a one per cent water solution of formaldehyde. The stalls may be cleaned by spraying or washing with a solution of bleaching powder (chloride of lime), six ounces to the gallon of water. Apply the following liniment to the udders of the affected animals after each milking: Olive oil thirty parts, and carbolic acid one part. White lotion (lead acetate) four ounces, zinc sulphate three ounces, and water one gallon, is very useful in case the udder is irritated and sore.

We hear a great deal now about breed type and characteristics, and it is right that breeders should pay attention to these things. But first and foremost the form and function that produce the most profit must be observed. We have seen breeders, in looking over pure bred animals—hogs for instance—entirely ignore a broad back, well filled hams, good length of body and strong, clean bone, and talk long and loud against the animal because one hind foot was black when they would rather have had it white to conform to the ideal marking. We agree that for a pure bred animal it would have been a good thing to have had it just right, but of the two—a white foot or a profitable meat-making form—we would certainly have greater admiration for the form. Usefulness must be the first requirement.

HER COMPREHENSIVE GLANCE.

Mr. and Mrs. Ferguson were passengers in an elevated train.

It whizzed past a house that was brilliantly lighted.

"I wonder what was going on there," ejaculated Mr. Ferguson.

"It was a wedding," replied his wife. "Didn't you see them standing before the preacher? The bride was in a white gown. The groom was in full evening dress. The bride wore a robe of chiffon cloth with bertha and yoke of duchesse lace on the bodice and lace flounce on the skirt. She had a full length tulle veil and carried a bouquet of lilies of the valley. Where were your eyes?"

Mr. Ferguson, realizing his utter worthlessness, resumed the reading of his paper and said nothing.—Chicago Tribune.

THE BEST WAY TO MAKE HAY.

The old adage about making hay while Old Sol is looking pleasant has a deal more of truth than poetry in it and just so to the practical farmer the smell of new mown hay suggests more than the pleasing sentiment of poetic fancy. Instead of breaking his back stacking hay or throwing it loose in a loft where it soon loses its sweetness, he puts it in bales and stores it away for future use or to sell at the most favorable market price.

Among the different hay presses manufactured for this purpose the line built by J. A. Spencer at Dwight, Ill., deserves special attention. Mr. Spencer manufactures several types of hay press, each of which possesses distinctive features which make it specially adapted to the purpose for which it is intended. Anyone sending a request to J. A. Spencer, Dwight, Ill., will be furnished with an illustrated catalogue fully describing these excellent machines. Mention the Cultivator.

Friendship, love and piety ought to be handled with a sort of mysterious secrecy; they ought to be spoken of only in the rare moments of perfect confidence, and to be mutually understood in silence. Many things are too delicate to be thought; many more, to be spoken.—Novalis.

THE JUBILEE POULTRY JOURNAL

A "Worth-while" Journal devoted to the Poultry Industry of the Pacific Coast. A Journal radically different, up-to-date and aggressive, advocating the cause of Better Poultry and More Profit.

Unusual contributions of great value, unusual competitions designed to stimulate, cultivate and educate the poultrymen to reach a greater success,—it is "Worth while," worth YOUR while and you should subscribe.

A Visit to the Large Packing Houses in the Eastern Cities

In Three Chapters.==Part I.

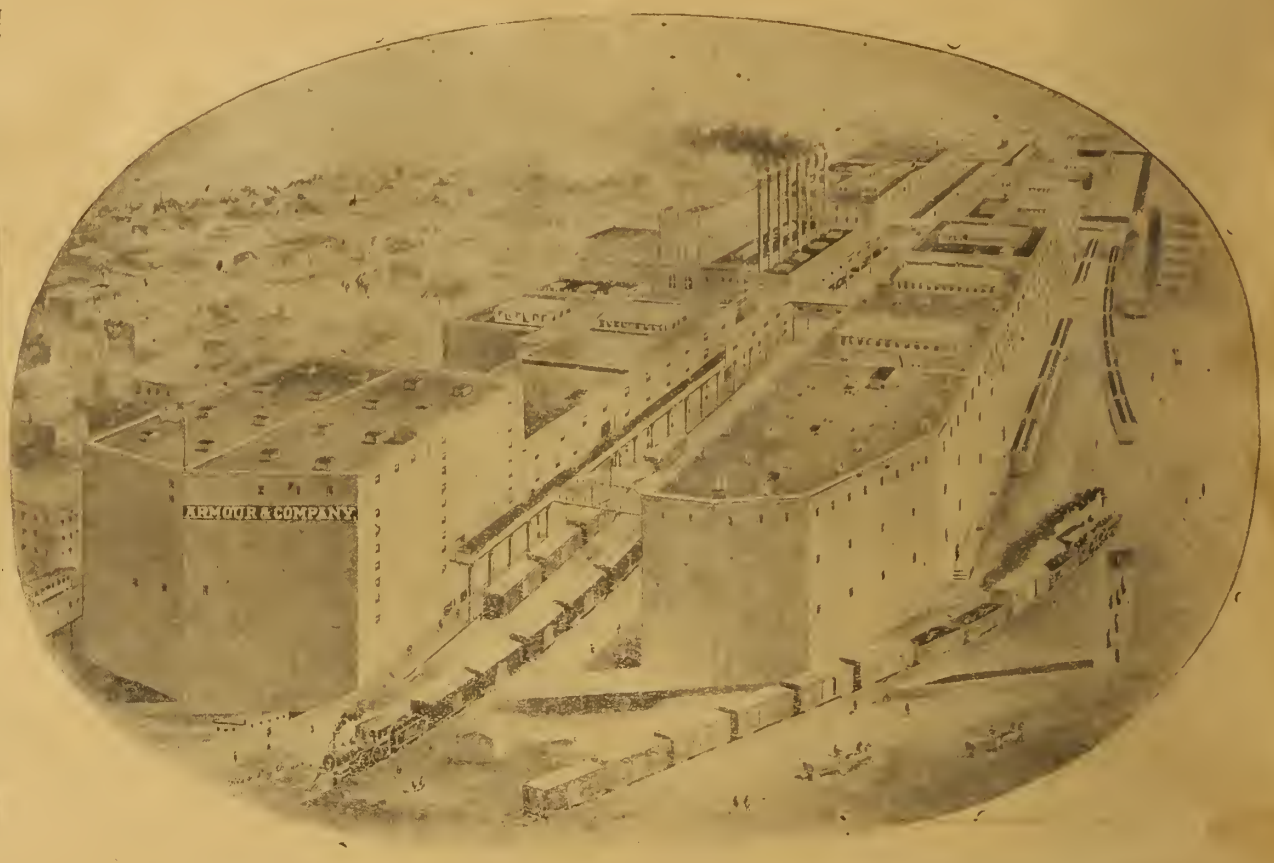
WILL HAVE BRANCH EAST.

Mr. A. R. Coulson, president of the Coulson Poultry and Stock Food Co., arrived home from the East on Saturday evening. Mr. Coulson had quite an extensive trip, stopping over a day or two at each of the following cities: Salt Lake City, Denver, Lincoln, Omaha, Kansas City, St. Louis, Chicago, St. Paul, Minneapolis, Spokane, Seattle, Tacoma, and also a week at the Portland Fair.

The Coulson Company is planning to establish another factory in Omaha, which will be a large institution. (From Petaluma Argus.)

Few people realize the magnitude of the packing house industry carried on in the east. Mr. Coulson's visit to the plants of the Armour Company and a few photographs taken of some of the principal parts, which we reproduce herewith, will give the reader some idea of the immense number of animals killed every day by the Armour Packing Company; and this is how they get so many hearts and livers to make the Heart and Liver Meal (animal meal) used in making Coulson's Special Dry Chick Food, Coulson's Egg Food, etc.

Mr. Coulson first visited the Armour Packing Plant at Omaha (see illustration.) Here they have a number of immense buildings, each occupied for different purposes and in their office building there are several hundred clerks taking care of the books and correspondence, etc., and an army of some 4000 men employed about the plant.



SHOWING PLANT OF ARMOUR PACKING CO. AT OMAHA, NEBRASKA.

HOGS COMING OUT OF SCALDING VAT AND SCRAPING MACHINE AND FIRST PROCESS OF DRESSING.

Mr. Capune, manager of the Animal Food Department, took the writer through the various departments, showing how the animals were killed, dressed, etc., all of which was very interesting. In one pile there was about 5000 hearts taken from the pigs and cattle that were killed that day, these hearts were cooked in a large steel tank that reached from the first floor to the fourth floor, and there were immense furnaces in the basement that heated up these tanks and cooked the meat therein. After the hearts were thoroughly cooked, then they were taken out and put into long boiler-like tanks, which had big revolving screws running through the center, and which kept stirring up the hearts until they were all crumbled up into a fine meal. These tanks were also heated up by furnaces underneath, so that the hearts were again thoroughly baked and dried. At the end of two hours the hearts were converted into a dark yellow meal, as dry as powder.

This Heart and Liver Meal is put in bags and every few days, or as soon as a carload is accumulated, it is shipped to the Coulson Poultry & Stock Food Co., at Petaluma, California, and is used in preparing **Coulson's Egg Food and Coulson's Special Dry Chick Feed.**

This Heart and Liver Meal is **great food to make chicks grow.** The Coulson Company uses lots of it in making Coulson's Egg Food, and Special Chick Food. There are many differ-

PROCESS OF KILLING AND SCALDING HOGS AT ARMOUR'S

Process of cleaning and dressing hogs. Also U. S. Government inspection and view of the chill room at Armour's.

ent poultry foods on the market, but the Coulson Company is the only firm that goes to the expense of getting such good material and they have the exclusive contract with the Armour Packing Co. for the Hearts and Liver Meal. No other firm can get any of it; therefore no other Poultry Foods are like Coulson's.

If you want success with poultry, feed the pullets and hens **Coulson's Egg Food** and feed the baby chicks **Coulson's Special Dry Chick Feed.**

Ask your dealer for Coulson's. Send to us for free poultry account book.

In the next issue we will tell about the Kansas City plant.

AT ARMOUR PACKING CO.

Loading cars of 400 sacks of Armour's Meat and Blood Meal for Coulson Co. The meat meal is made from hearts and liver, baked to a crisp and ground fine. The Coulson Co., Petaluma, Cal., has a contract to take the entire product of this meat meal and it is used in preparing Coulson's Poultry Foods. Ask your dealer for Coulson's Egg Food and Coulson's Special Dry Chick Feed.

Feed the Chickens Coulson's Feed

There's Nothing Better

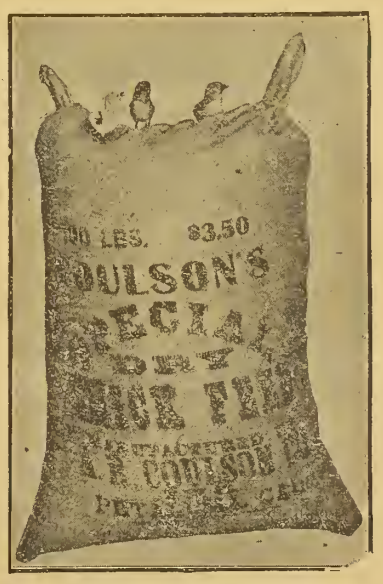
PHOTOGRAPH SHOWING

A HUNDRED THOUSAND BAKED AND DRIED HEARTS AND LIVERS

These are ground up into small pieces and used in mixing COULSON'S SPECIAL DRY CHICK FEED AND COULSON'S EGG FOOD.

A sack of Coulson's Egg Food.

A mixed feed for chickens to make the hens lay lots of eggs. This feed is composed of about three-fourths ground grains or mill feeds and nearly a quarter of animal meals, that is fresh, fine ground bone, dried blood and the heart and liver meal.



You will have the best success you ever had in raising chickens if you will feed COULSON'S SPECIAL DRY CHICK FEED. Send for sample. It's good for turkeys as well.

FOUR T'S.

There are four T's too apt to run,
'Tis best to set a watch upon:

Our Thoughts.
Oft when alone they take them wings,
And light upon forbidden things.

Our Temper.
Who in the family guards it best,
Soon has control of all the rest.

Our Tongue.
Know when to speak, yet be content
When silence is most eloquent.

Our Time.
Once lost, ne'er found; yet who can say
He's overtaken yesterday?

THE DOG'S COLD NOSE.

When Noah, perceiving 'twas time to embark,
Desired the creatures to enter the Ark,
The Dog with a friendliness truly sublime
Assisted in herding them. Two at a time
He drove in the Elephants, Zebras, and Gnus
Until they were packed like a boxful of screws—
The Cat in the cupboard, the Mouse on the shelf,
The Bug in the crack. Then he backed in himself;
But such was the lack of available space,
He couldn't tuck all of him into the place;
And so, though the rivers rushed over the plain
And down from the heavens fell blankets of rain,
He stood with his muzzle thrust out through the door
The whole forty days of that terrible pour!
Because of which drenching, the Sages unfold,
The nose of a healthy Dog always is cold.

—N. Y. Times.

The Fate of a Rescue Party.

Gertrude Ellerton looked at the girl who had just announced her intention of stopping for the night with dismay in her heart, if not in her face. Constance Farrar was her very dearest friend, and she couldn't remember a single other time when she hadn't been glad to see her; but when one is planning to elope at 10:30 with some one a good deal dearer than even a dearest friend one naturally views with distinct disfavor the advent of an all night guest.

Gertrude put in a very bad quarter of an hour, during which she said sweetly hypocritical things to Constance and tried to decide what to do. In the end she made a virtue of necessity and confessed.

Coustance was surprised and pained, for she was very fond of Gertrude.

To remoustrate would, she well knew, be worse than useless. She could not report to Papa Ellerton, for the far-seeing Gertrude had prudently sworn her to secrecy. And naturally it was physically impossible to forcibly detain her misguided friend under the paterual roof.

Clearly the situation was one calling for tact and diplomacy, and that of a Machiavellian order. Constance, under pretense of examining the photos on the mantelpiece, set the clock back an hour, Gertrude, nervously putting various articles of wearing apparel in a trunk, and guiltily afraid of interruption by her mother or her small sister or her middle-sized brother, was comfortably unconscious of the sudden flight of time backward.

Once, to be sure, she glanced at the clock and remarked with puzzled frown that "it seemed later than that."

But Constance promptly and smoothly suggested that that was because "You're so anxious to see him, dear." And Gertrude unhesitatingly accepted the plausible explanation.

When the hands of the clock pointed to half past 9 Constance put on her wraps and kissed her friend.

"I really must not stay another minute," she said. "If I'm here when you go your mother never would forgive me; she'd think I ought to have stopped you. Goodby, dear, and good luck."

When the street door closed behind her, Constance pulled the high collar of her fur jacket well up about her face and started resolutely for the corner where she knew an impatient lover and a closed carriage were awaiting the misguided Gertrude. She shivered, but less from cold than from nervousness. For despairing of all other means of saving her friend, she had decided upon an appeal to the gentleman in the case.

Then a man came quickly out of the shadows, and a strong, masculine hand closed over her arm and hurriedly assisted her into the waiting carriage. She had a moment of uncontrollable fright lest his lover's instinct would warn him that he was eloping with the wrong girl.

But it didn't, and with a soft little sigh of relief Constance settled into her place and prepared to repel any proffered familiarity on the part of her companion. But it seemed that there would be none to repel, and she was conscious of a distinct feeling of disappointment and disapprobation. She had had no experience, of course, but she had a woman's instinct of what would have been fitting to the occasion, and she wondered that Gertrude should have selected a man who hadn't the courage to venture even a mere handclasp.

Finally, in sheer desperation, she leaned forward, bringing her face well within the circle of light cast by one of the infrequent electric lamps they passed. To her surprise she found herself staring full into the eyes of her companion. They were very attractive eyes, and seemed somehow to match their owner's smooth-shaven face and square, determined chin.

"What a nice face he has," flashed through Constance's mind. And then, to her unspeakable dismay, she realized that quite involuntarily she had spoken the words aloud.

"Am I to infer," inquired a deep and very pleasant voice, "that you are referring to my face?"

Constance, blushing furiously at the very personal nature of her opening remark, was obliged to admit that the inference was correct. Then she hastened to make bad worse by saying, "You don't look like a person who would elope."

"Of course I wouldn't elope with any one," he said, with the air of a person determined to please even at the cost of veracity. "Except the one girl," he amended hastily, for Constance's uncompromising attitude was a thing to be felt.

"Oh!" said Constance feebly. And the conversation languished.

Irrationally enough, Constance found herself almost liking her companion. But she was angry with him, too. Actually the man had said no word concerning Gertrude; he had not even seemed surprised that she should be taking Gertrude's place.

"I want to speak to you concerning Gertrude," she said.

"Yes?" said the man coolly. "Which Gertrude? Gertrude who?"

"Gertrude Ellerton, of course," snapped the enraged Constance. "I want to know if you think it right for her to elope?"

"Good heavens, no!" said Gertrude's fiance very decidedly.

"Then," demanded Constance hotly, "will you kindly explain why you're helping her to do it?"

"I'm not," denied the man promptly.

"No," agreed Constance scornfully, "just at this moment you're not. But it's no fault of yours, nor hers, either."

The man at her side ejaculated something that might easily have been interpreted as expressive of any one of half a dozen different emotions.

"My dear young lady, would you mind telling me just who you are?"

"I'm Constance Farrar," said the owner of that name, in the tone of one issuing a challenge, "and I'm here to prevent your elopement with Gertrude."

The effect of her words was not precisely what Constance had anticipated. The gentleman at her side, after a heroic but ineffectual struggle, abandoned himself to uncontrollable mirth. Constance glared at him. She was unable to detect any humor in the situation, and she said so.

"You don't see the joke now, of course," he said. "But you're going to. I'm not Raymond Fenton, as you seem imagine. I'm Albert Worthington, and I'm here to prevent your elopement with Fenton."

There was a moment of astonished silence on Constance's part, then she giggled nervously. "Good gracious!" she said, "who would have dreamed of such a thing?"

"It is rather a peculiar coincidence," agreed Worthington, "that the spirit should have moved us both to go into the rescue business at precisely the same time in exactly the same manner. By the way, would you mind telling me how you got here in Miss Ellerton's place?"

"I set her clock back an hour," Gertrude confessed.

"Concidence No. 2," said Albert Worthington, cheerfully. "I juggled with Fenton's watch to precisely that extent.

"I'm most awfully glad," Worthington went on, "that it wasn't you that Fenton had planned to elope with."

Constance blushed again. She felt that she ought to be angry, but she wasn't.

"I say, Miss Farrar," proposed Worthington, "let's go and see them off. First, they'll go to hunt up a clergyman, then they'll show up down at the station. We couldn't miss them even though we tried."

It is really astonishing how well acquainted it is possible for two people to become in a very short time. When they left their carriage at the station Worthington drew Constance's hand through his arm with a manner that was distinctly proprietary. And it was evident that Constance in no way resented the proprietorship.

"We're forgetting," said Worthington, "that we've made them lose an hour and miss their train into the bargain. I suggest that we reconnoiter a bit before telling them."

Constance assented, and from behind a sheltering post, they behild the newly wedded ones. They were seated side by side, oblivious of time or place.

"The great moon-struck idiots," whispered Worthington. "I don't believe they even know they've missed their train."

WANTED

A Bright Young Man with Light Team in your county. Steady work and good wages for the right man. References required. For full particulars, address KOCH V. T. CO., Box C, WINONA, MINN.

HELP!

Settle Your Own Country

The Santa Fe is doing its share in trying to send more farmers to your country. You can help that work by a little effort.

Every reader of this notice is requested to send to the undersigned a list of his friends in the East who may possibly be interested. Literature regarding your country will be mailed to them, and any questions they ask will be fully answered.

Send list this week to

WILLIAM NICHOLSON,
General Colonization Agent, A.T.& S.F.Ry
Railway Exchange, Chicago

1007 N. ALAMEDA, LOS ANGELES

When writing advertisers mention Cultivator.

But Constance with shining eyes, whispered, "I'm so glad we didn't stop them."

"Yes," Worthington answered. "But I'm more than glad—I'm thankful that we both tackled that rescue business. Otherwise—," His tone and eye were eloquent.

He gave Constance's arm a quick, light pressure. "With your permission," he said, "I'm coming to call tomorrow, and, the day after and all the other days, too."

The permission was not withheld.—Denver News.

Cookery Recipes

Cucumber Pickles and Preserves—The cucumbers must be ripe for both these preparations. For the pickles, peel the cucumbers, remove all the seeds, and slice the cucumbers in long thin slices. Put them into salted cold water for 24 hours. Then remove from this water, drain, place in cold fresh water for four hours. To every eight pounds of the cucumbers, use two pounds of sugar, one pint of vinegar, one ounce of cinnamon, one-half ounce of allspice, one-half ounce of mace, one-half ounce of ginger root. Mix these spices well together. They should all be ground spices. Tie them in little bags, heat them with the vinegar and sugar. When the syrup is hot put in the cucumbers, place on a large dish and pour over them the syrup. The next day heat the syrup only to boiling and pour again over the cucumbers, Repeat this for four mornings. The last day, boil both syrup and cucumbers together and seal in jars.

If the pickles are desired less sweet omit one pound of sugar and more vinegar can be used.

This recipe can be used for peaches, pears, quinces, watermelon rind, plums, etc.

For the ripe cucumber preserves prepare the cucumbers as in the other recipe, but omit the vinegar and increase the sugar to four pounds of sugar to eight of the cucumbers and be careful to boil the syrup so as to reduce if it should seem at all thin, and at the last time of boiling seal up the cucumbers while hot.

* * *

To Can Pumpkin.—To can pumpkin, wash the pumpkin, cut into pieces, cook in water until the rind seems soft, remove from fire, drain; when cool enough to handle comfortably, remove the rind, return the pumpkin to the stove and cook until it is perfectly soft and the water seems all out of the pumpkin. Stir well so that there are no lumps and add a little salt. Have your glass jars and covers well sterilized with boiling water and hot. Fill with the pumpkin, stir with a silver spoon around the inside of the jars after they are filled, so that no air is left in the jars, fill perfectly full and seal. Leave them bottom sides up in the warm kitchen for 24 hours, then if they seem perfectly air tight, put in a cool dark place. Squash can be canned, and is very useful as a vegetable in winter.

* * *

Sweet Potato Pie.—Make a good paste (it need not be as rich as puff paste), line the pie dish, which must be a deep one. Wash and parboil two good sized sweet potatoes (I think one pint of the potatoes after they are grated), when they are cold, grate them. eBat together until very light 1 tablespoonful of butter, ½ a cup of sugar and the yolks of 3 eggs. Add to this mixture 1 cup of rich milk, 1 teaspoonful of cinnamon. Fill the pie dish and bake the pie for 30 minutes or until the custard seems firm; then whip the 3 whites of the eggs until light, add 2 tablespoonfuls of sugar, spread this over the top of your pie, return to the oven long enough to make the meringue a light brown. If you do not care for the meringue use the whites of the eggs with the yolks in the pie.

* * *

Irish Potato Pie.—Line a deep pie dish with paste. Mix together 1 pint of mashed potatoes, made very smooth, seasoned with a little salt and butter and ½ a teacup of cream, ½ a cup of butter to the mashed potatoes while they are hot; when cool add the juice and grated rind of 1 lemon, 1 tablespoonful of brandy and 3 eggs well beaten. Mix together and fill the pie dish, bake 30 minutes or until the pie seems cooked.

HOMELY HINTS.

Dry Cleaning Hints.—Cleaning with gasoline can be successfully accomplished at home, if great care is taken in its manipulation. A silk waist, or a dress must first be thoroughly shaken, so that no dust remains in the material. You need a quantity of gascline so the garment to be cleaned can be all covered and worked up and down in the gasoline. Do this until the garment looks quite clean, then rinse it in an equal quantity of gasoline and hang the garment in a current of air to dry quickly. The odor will soon vanish and your garment look fresh and clean. The gasoline used should be strained and bottled, tightly corked, for future use.

I saw a tailor gown of heavy broadcloth treated in this way at home and the result was satisfactory.

Professional cleaners use soap, washing the garments in gasoline and castile soap, or any pure white soap. Try a little bit of the goods first. Thrifty housekeepers may take advantage of this knowledge.

But a word of caution. Use the gasoline in a room where there is no fire.

* * *

If your picture frames have become tarnished and have lost their fine appearance from dampness and the flies, they can be restored by taking the white of an egg, beating it a little and applying it to the frame. If the frame is badly fly spotted, use alcohol applied to the spots by a soft brush, then rub the spots gently with a soft, clean cloth. If the gilding is very dull, it may need to be washed over with a weak solution of lye and water, not too strong or the gilding may come off. Dry the frame with a piece of clean linen at once after applying the lye and water solution.

Soap and chalk mixed together and rubbed on spots of mildew will remove them.

Borax will drive away ants from the pantry shelves if sprinkled freely on the shelves.

Try two drops of camphor on your toothbrush when cleaning your teeth in the morning. You will find your mouth after with the freshest, cleanest possible feeling imaginable and your gums rosy. The camphor prevents cold sores also.

If your lamp is oily on the outside, a most annoying thing, look and see if the wick is turned down below the burner. If it projects above the burner the oil is bound to feed it and it must run over the surface if unlighted.

PICNICS OF THE FUTURE.

"Let us suppose a railway to have been built between the earth and the fixed star Centauri," said a lecturer. "By a consideration of this railway's workings we can get some idea of the enormous distance that intervenes between Centauri and us.

"Suppose that I should decide to take a trip on this new aerial line to the fixed star. I ask the ticket agent what the fare is, and he answers:

"'The fare is very low, sir. It is only a cent each hundred miles.'

"'And what, at that rate, will the through ticket one way cost?" I ask.

"'It will cost you $2,750,000,000,' he answers.

"I pay for my ticket and board the train. We set off at a tremendous rate.

"'How fast,' I ask the brakeman, 'are we going?"

"'Sixty miles an hour, sir,' said he, 'and it's a through train. There are no stoppages.'

"'We'll soon be there, then, won't we?' I resume.

"'We'll make good time, sir' said the brakeman.

"'And when will we arrive?"

"'In just 48,663,000, years.'"—Exchange.

WHAT BOYS SHOULD LEARN.

There are a great many things boys, while boys, should learn. And if they learn these lessons so well as never to forget them during life, they will prove of great help to them oftentimes when they need help.

Among other things boys should learn, these may be named:

1. Not to tease boys and girls smaller than themselves.

2. Not to take the easiest chair in the room, put it in the pleasantest place, and forget to offer it to mother when she comes in to sit down.

3. To treat mother as politely as if she were a strange lady who did not spend her life in his service.

4. To be as kind to their sisters as they expect their sisters to be to them.

5. To make their friends among good boys.

6. To take pride in being a gentleman at home.

7. To take mother into their confidence if they do anything wrong, and, above all, never to lie about anything they have done.

8. To make up their minds not to learn to smoke, gamble, or drink, remembering these things are terrible drawbacks to good men, and necessities to bad ones.—The Glenwood Boy.

CONFIDENCE OF OTHERS.

A girl who has been taught by her mother to respect the confidence of others learns at the same time how safe her own will be in her mother's loving care. In the desire for complete confidence between mother and daughter, neither should forget that a due reserve is both necessary and desirable in regard to the confidence of other people. No girl should repeat, no mother listen to anything which has obviously been said to the girl alone. Besides, a desire for unlimited confidence is a sign of weakness on both sides. A certain amount of reserve is the hall mark of all strong characters.

FACTS FROM THE BUSY WORLD.

The population of the world is now estimated to be 1,503,300,000.

Waste leather is no longer thrown away. Manufacturers use it, in compressed form, instead of iron, to make cog wheels.

The Ambidextrous Society, of London, has been formed with the object of encouraging people to use both hands with equal facility.

NOT WEBSTERIAN.

"Yep," answered Paul in school one day; and when his teacher heard
His strange response, to punish him, she bade him seek the word
Within the dictionary. After she had let him grope
In vain for it, she asked him, "Is it there?" And Paul said, "Nope."
—Woman's Home Companion.

Delicacy is to the affections what grace is to the beauty.—Degerando.

PEAR BLIGHT.

(Continued from First Page.)

blight bacilli to the terminal flower cluster on the smaller or outer branches, which, if affected, may be removed without serious loss of wood. These two steps embody the essence of the Waite method, which has been successfully practiced by Dr. Waite not only upon his own orchard in Maryland, but in various others throughout the country, on which he has experimented. If carefully followed, there is a reasonable prospect that anyone may succeed in time in freeing even an old orchard from blight by severe pruning and the re-establishment of the trees in the manner stated, while it is much simpler to keep a newly-set orchard permanently free from serious injury. Yet in either case there must be more or less isolation of the plat from outside sources of infestation.

6. **Burning Refuse.**—Since the germs retain their vitality for a long time, care must be taken to burn systematically and thoroughly all pruned wood and leaves and to keep the orchard at all times free from them.

7. **Sterilizing Implements**—Also, as the bacteria are readily communicated by inoculation, it is advisable, if not necessary, to sterilize the pruning shears and saw after each amputation, that the germs may not be communicated to the healthy tissue on another limb or on another tree. Sterilization may be effected by dipping the tool in a 5 per cent solution of either carbolic acid or formaldehyde, or by wiping the blade with a cloth dampened with the solution.

8. **Spraying**—Spray the trees, just as the buds begin to expand, and once a week thereafter for four or five sprayings (except during the actual blooming period) with Paris green for the destruction of the Diabrotica, which, it is believed, assists in spreading the bacteria. Use 4 ounces of the arsenite to 5 pounds of lime and 50 gallons of water, or, preferably, mixed with 50 gallons of Bordeaux.

THE BEAUTIFUL CAMPING SECTION.

The Cultivator has often spoken of a productive and beautiful section to the north of San Francisco, within a short distance of the California Northwestern Railway. We note that the section during the past summer has had a great many visitors from San Francisco and vicinity. This is especially true of the Russian river section, some seventy-four miles from San Francisco, on the Northwestern. This ideal spot for summer homes has been subdivided into large lots, which are offered for sale for from $50 to $150. The section is in close proximity to the best of hunting and of fishing and abounds in delightful drives to various camping sections, both in mountain and along the river. No other section in California affords finer scenery and more delightful climate for summer camping. A card dropped to the California Northwestern Railway, Mutual Life Bldg., San Francisco, will secure information regarding advantages of this section, also of some of the agricultural sections along the line of that railway.

BRAN—Per ton, $22.50@23.50.

CRACKED CORN—Choice stock. per ton, $30.50@31.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $26@29.

GROUND BARLEY—Per ton, $21@23.

COCOANUT CAKE—In lots of 10 tons. $20.50; 5 tons, $21; less quantity, $21.50. Prices are mill rates and are subject to change without notice.

Flour and Cereals.

FLOUR—Net cash, Family, Extra, $4.80@5.10 per bbl; Baker's Extra $4.70@4.90; Oregon and Washington, $3.80@4.60.

WHEAT—No. 1 Shipping, per ctl., $1.30@1.35; inferior grades, $1.15@1.30; White Milling, good to choice, $1.35@1.45 for new and higher for old.

BARLEY—Choice, No. 1 Feed, $1.02½@1.07½; some fancy grades up to $1.08¾; common to fair, 97½c@$1; inferior grades, 87½@95c; Shipping and Brewing, $1.10@1.12½; Chevalier, $1.10@1.20.

OATS—Good to choice White, $1.37½@1.45; Red, $1.35@1.45 for choice to fancy; $1.15@1.32½ for common to fair; Black, for seed, $1.50@$1.65.

RYE—Good to choice, new, $1.42½@$1.47½.

CORN—Good to choice, per ctl: California, new, large Yellow, $1.40@1.45, small do, $1.60@1.65; White, $1.37½@1.40; Eastern, Yellow, $1.40@1.42½; White, $1.40@1.42½; mixed, $1.37½@$1.40.

CITRUS MARKETS

The citrus fruit market in eastern auctions is, if anything, rather easier, which has been largely caused by the indifferent quality of the fruit offered. Especially is this true of grapefruit and of oranges. Lemons have reduced somewhat in price, the importation having increased very materially, though the few cars which have been offered have commanded very satisfactory prices, though not equal to those of a month ago.

New York.

At Monday's sale two cars of oranges and three cars of lemons were sold. The quality was, as a general thing, indifferent, though the finer grades advanced in price. Two cars of grapefruit were also offered, selling very low. Grapefruit from Jamaica is beginning to arrive and it is claimed will take precedence over California stock.

In Valencias, I X L, Spence Ft Co, averaged $3.75; Blue Seal, xf, ACG, $5.50; Red Shield, xc, do, $4.15.

Lemons, KCFE, Santa Paula, $5.60; Triple x, fy, Whittier, $6.20; Triple E, Whittier, $5.10.

Market somewhat firmer at Tuesday's sale, some fruit advancing to $7; two cars oranges and three cars of lemons were sold. Valencias, Old Mission, fy, Chapman, Placentia, $6.30; do, ch, $5.60; Golden Eagle, st do, $4.50;

Lemons—Flower, fy, Upland, $4.20; Lomas, ch, Santa Paula, $4.25.

Five cars sold Wednesday at auction, three of them being lemons. Valencias, only fairly good stock, and while prices were not big, they represented full value, quality considered. Grapefruit still at ruinously low prices. Large receipts of foreign lemons tended to ease the lemon market, though the prices continue fairly satisfactory.

Valencias, Rialto Girl, fy, $4; Golden Rule, xc, Riverside, x, $4.50; Grapefruit, Golden Rule, $1.20.

Lemons Triple X, fy, Leffingwell, Whittier, $4.95; Triple E, do, $3.90.

Boston.

Only one car of Valencias offered at Monday's sale. Prices ranged from $1.85 to $3.75 per box.

Only one car was offered at Tuesday's sale, quotations ranging from $2.75 to $4.40.

At Wednesday's sale, two cars of oranges and one car of lemons were sold, lemons manifesting a very strong tone. Prices ranged from $3.45 to $4.25. Valencia oranges ranged $2.35 to $4.15.

CITRUS SHIPMENTS.

Total shipments of citrus fruits to date, 30,021 cars, of which 4181 were lemons.

The Droge packing house at Fresno was destroyed by fire last Saturday, causing a loss of $100,000. The building and contents, mostly dried fruit, were insured for about $75,000.

The weather and corp conditions for the week ending September 18, are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

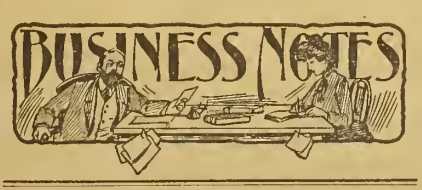
General Summary.—Clear and warm weather prevailed in all parts of the State most of the week, although the temperature was slightly below normal in the great valleys. Light rain fell in the northern coast counties Tuesday morning and again Sunday morning. Fogs prevailed to some extent in the coast sections at night.

Conditions were generally favorable for maturing the late fruits, raisin making and fruit drying. The first crop of raisin grapes in the San Joaquin valley is mostly on the trays and curing satisfactorily. If the weather continues favorable the raisins will be ready for the packing houses in a few days. Raisin making has commenced in Southern California. Raisin grapes are reported excellent in quality, but the yield in some sections is below average. Wine grapes appear to be more abundant and the wineries are running to their full capacity. Heavy shipments of table grapes are being made. Prune harvest is not quite completed, but most of the crop has been dried or is now on the trays; the yield is lighter than anticipated, but the fruit is of good size and quality. The apple crop will probably be the best for several years, both in quantity and quality. Oranges continue in excellent condition in all sections and the crop will probably be the largest ever raised in the State. Walnuts are opening and harvest will commence soon. Melons, guavas and almonds are yielding large crops.

Hop picking and baling are still in progress; in some sections the crop is fully average and of good quality. Bean harvest is in progress in all sections and reports indicate that the crop will be very large. Sugar beet harvest continues. The fourth crop of alfalfa is being cut. Dry seeding has commenced in the Sacramento valley.

Eureka Summary.—The weather along the coast was generally favorable during the week. Continued warm and dry weather in the interior, where feed is short. Late varieties of apples are good and shipments are large.

Los Angeles Summary.—The mountain apple crop is being harvested under favorable conditions; the crop is large and of good quality. Grapes are plentiful; size and quality good. Oranges are not maturing as rapidly as last season and Thanksgiving shipments are not expected to be heavy.



MUST HATCH.

The Must Hatch Incubator Co., of Petaluma, is out with a 36-page catalogue which contains "something about incubators—and some besides. It has illustrations of various incubators, brooders and appliances of the incubator room where 50,000 chicks per month may be hatched and many other illustrations. Mr. Bourke, president and manager of the com[illegible] is to be complimented on the growth of this big concern. The Must Hatch incubators are securing a world-wide reputation for good work.

MOLINE RUNABOUTS.

Mr. Gregory tells us that those "Moline Runabouts" are beauties. Still better, we ran down to see them and we know they are beauties. Four seats, genuine leather upholstering, divided front seat, detachable side entrance tonneau, twelve-horse power, good for 30 miles per hour. Efficiency and beauty combined. All for $950 while they last, that is, this one car which is now in stock.

The Idyllwild Bungalow will close its dining room on Tuesday, September the 26th, although cottages and tents furnished for housekeeping can be had all the year round. The management reports a very successful season, the business having been about twice as large as any former year. The company will build more cottages, improve the roads, double the capacity of their bowling alley, erect a lecture and entertainment hall and put in a completely equipped livery stable. The summer season will open again in June, 1906.

The Clifford Chemical Co., of Los Angeles, are advertising a new cure for lump jaw, a hog cholera remedy and a chicken cholera and roup remedy in the Cultivator. Dr. C. E. Clifford, a veterinary surgeon and dentist, is senior member of the company, and his diplomas and recommendations are first class.

Mrs. J. L. Updyke, of Fullerton, is a new advertiser in the Cultivator. She recently bought the fine flock of White Leghorns of Jacob Kreger, of Anaheim, and is now offering eggs from them.

R. E. O'Neill, the U. S. gauger at Maderia, closed down the Italian-Swiss winery at that place. He claimed the employes of the winery were selling liquor in retail quantities.

DOUBLE CAM BRADLEY STEEL HAY PRESS
One horse can operate it. Very easy for two.
Send for circular.

PICKING OLIVES IN DECEMBER IN A SAN JOAQUIN ORCHARD.

The annual output of olive oil in California is about 150,000 gallons; of pickles 230,000 gallons. The imports to the country of oil amount to about 1,250,000 gallons per year and of pickles to 2116 gallons. In consideration of the fact that it is 135 years since the olive was introduced into California, it should be producing more of these products and the country importing less. In quality the California products beat the world.

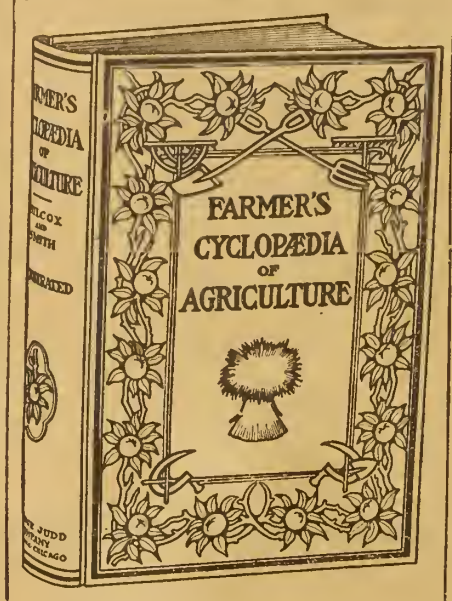
Farmer's Cyclopedia of Agriculture



A Compendium of Agricultural Science and Practice on Farm, Orchard and Garden Crops, the Feeding and Diseases of Farm Animals, Dairy Farming, and Poultry in the United States and Canada

Authors: EARLEY VERNON WILCOX, *Ph. D.*
CLARENCE BEAMAN SMITH, *M. S.*
Assistant Editors in the Office of Experiment Stations, United States Dept. of Agriculture

The World Moves

and whoever would not be left behind must lay hold on every means that enables him to move with it. As a basis of one's efforts nothing is more essential than the possession of a good work of reference

Adapted to the Conditions Peculiar to California and Adjoining States

The Farmer's Cyclopedia embodies in its many articles, most of the results of years of painstaking work at the California and neighboring State Agricultural Experiment Stations. It is thus, in effect, both a digest of local and state experience, and a compendium of general knowledge, all of which will prove of indispensable helpfulness to everyone in this section.

The Last Twenty Years of Progress

have measured more changes and recorded more advances in every branch of agricultural science than have been achieved during the hundred years preceding. During all these years no reference book adequately covering the subject has been issued.

The plan of this work is most comprehensive. Every article has received the most careful preparation at the hands of the authors, who have enlisted the co-operation of the highest authorities in the various departments. The greatest educators of the world, representing every branch of agriculture, here unite in one immense faculty to present directly and plainly the pertinent facts of their specialties. Every statement is authoritative and absolutely reliable.

If you wish to know about field crops, garden vegetables, fruits, nuts and other economic plants, farm animals, dairy farming, poultry, also manures, fertilizers, principles of feeding, soils, drainage, irrigation, spraying, veterinary medicines, etc, etc, it is here. Everything concerning farm matters is treated with great thoroughness, though without undue fullness. We claim for it the unique distinction of presenting for the first time, in a carefully arranged and perfectly accessible form, an accurate summary of every subject of interest to farmers, etc.

Over 6000 Topics Indexed
A Wealth of Illustrations

An important part of this work is its very complete and elaborate index, with cross-references under both scientific and common names, so that any information wanted can be found at once. There are between 6000 and 7000 topics covered in these references, making the most perfect index to agriculture ever attempted. It contains 700 royal octavo pages (9½ x 7 inches) and nearly 500 superb half-tone and other original illustrations. Type, paper, printing and binding are all in the highest style of the bookmaker's art, worthy alike of the well-qualified authors, the enterprising publishers, and the industry of agriculture.

PRICE IN HALF MOROCCO, $4.50

To Cultivator readers we make this proposition:—Fill out and sign the enclosed coupon and mail to this office and the book will be delivered postpaid at once and your Cultivator subscription advanced one year.

Silo Construction

A Few Notes on the Value of Ensilage and an Interesting Letter from E. E. Moore on Building and Filling

Never before has the Cultivator received as many requests for information on the silo and ensilage as this season. It is often claimed that California, with its perpetual summer, has no need for the silo, but the great advantage which the few have found in it is gradually extending its use. This paper has often referred to these advantages and only recently asked one of the largest dairymen near Los Angeles if it was a mistake to urge California dairymen to build silos, and he answered, "By no means. The silo is of the greatest advantage to any dairyman with ten or more cows."

It is of advantage because of the great value of the food and because so much can be grown on a small plot of land. As a rule corn is used for silage. Some use alfalfa of first cutting, which is often so full of foxtail and weeds as not to make good hay. Sorghum is sometimes used, but is by no means the favorite which corn is. An eastern paper gives the following as a limit as to when to cut the corn:

"Corn for silo should be cut when the most advanced ears are well dented and the lower leaves of the corn stalks are beginning to dry. If it is cut much before this, the silage is apt to be of poor quality. It will develop too much acid and consequently be sour. There is more nutriment in corn if cut at the proper time, than if it is cut too early. If it should so happen that the corn is too ripe and somewhat too dry to make good silage, a stream of water can be run into the silo when it is being filled. There is but little danger of running in too much water."

As to silo construction, we give the following, written for Cultivator readers by E. E. Moore, of Compton:

* * *

Editor Cultivator: I have no doubt that some of your readers who are dairymen do not own a silo, and perhaps do not believe it much good. On this point I would say that anyone owning ten cows would add at least $20 per cow per annum to the earning capacity of his herd by feeding say 30 to 40 pounds daily of corn silage. I began its use about six years ago when I owned ten cows. I constructed a square silo in one corner of my hay mow by nailing number two, six-inch flooring to 2x6 studding 24 feet long. I placed the flooring with the groove up and filled this groove with heavy paint. In each of the corners I put a 2x8 beveled at the mills, so that the sharp angle of the box was cut off. This silo holds about 50 tons and has been in use ever since it was built.

A couple of years ago I put up a stave silo outside of the barn; this was constructed of 2x6 rough redwood, is 30 feet high and contains perhaps 75 tons. The silage in this tub has been equally as good as in the square one. This fall I have constructed two other stave silos, one of 100 tons capacity, and the other of 60 tons, so that I now have close to 400 tons capacity for my 100 cows.

So much for the silo. I might say, however, in passing, that none of these silos cost me over $100 and some as low as $60.

Another good style of silo is made by ripping fencing into one-half inch stuff and putting tarred paper between. I am told this makes a cheap, easily constructed silo of great capacity and durability. I am inclined to think that I shall try this style when I increase my silage capacity, as I surely will by another season.

Now as to filling: I first used a No. three Lambert engine and No. 131 cutter. This machine would put up about three tons per hour. Then I got a six-horse power Lambert and No. 18 Ohio, having sold the old one. I now have a Climax blower and cutter, which is run by an 18 horse-power White & Middleton engine, and with this last machine I have put through 45 tons in 180 minutes, or a ton every four minutes. Where one does not desire to go to the expense of buying the machinery he can easily hire it cut at 30c per ton. One peculiarity about the work of the Climax cutter I have noticed is that the stalk is entirely crushed and shredded besides being cut, so that a silo will hold much more and the cows do not leave any because of sharp edges or chunks.

A very common mistake in the preparation of silage is made in putting it up too green. When this is done the succulent juices will run to waste and much of the food value is destroyed. If the corn is kept well irrigated and growing it is best to have the ear pretty hard. Of course, when the lower blades die and the lower part of the stalk gets yellow, it is not right, but this will not occur if kept in good growing condition up to the last.

I have always fed my cows at noon, thus keeping away any unsavory odors during milking. I find that they require from thirty to forty pounds per head. I always figure my silage in at $3 per ton. If one has to buy the corn and hire it cut, it may cost perhaps $3.50 per ton, and where one raises all the corn and has his own machinery, the cost would not exceed $2.50 per ton. When fed in conjunction with beets and alfalfa hay, you have a perfect ration and one that will develop to its fullest the capacity of your herd. Any single ration must necessarily be unsatisfactory and consequently unprofitable. I always salt my silage so that the cows eat more and drink more perforce, and this adds greatly to their milk production. I have also salted my alfalfa hay this year and I believe it will be found satisfactory. I have been handling dairy cattle now for ten years, and some of the best cows on the coast with pedigrees equal to King Solomon's, and I find that they all take to silage like a duck to water, and with unvarying good results. Not only is the quantity of milk increased but also the test is very perceptibly higher when feeding silage,—E. E. Moore, Compton.

GREEN ALFALFA FOR COWS.

What is a safe ration of green alfalfa for cows? I have lost several good cows that were allowed to run in alfalfa. Did the alfalfa kill them? I would like to have the best information regarding the construction of the silo, especially with regard to feeding alfalfa.—John Neilson, Hollister.

Green alfalfa will certainly kill some cows if they are allowed to feed upon it when it is young and succulent or when it is wet. This is especially the case if they have been kept on dry feed and are turned into a fresh pasture of alfalfa, when they will gorge themselves with the young feed till digestion is suspended, fermentation sets in, and they bloat to that extent that they are choked to death or possibly by actual rupture of paunch. Remedies for this disease, hoven or bloat, have been given in the columns of the Cultivator, but unless the pasture is near the house where the animal's distress is observed early in the trouble, it will probably die before help arrives. A good, big dose of common cooking soda will relieve a mild case. Some use a common rubber garden hose well greased and forced down the throat to allow the escape of the gas. Others tie a broom-stick in the mouth to hold the mouth open, while in severe cases, some have had complete success by the use of the knife in punching a hole in the paunch. The best way is to prevent the trouble by turning the cattle in the alfalfa pasture only a part of the day, when the sun has dried the leaves of moisture. Some dairymen even go so far as not to give the cows more than thirty minutes run in the alfalfa field. If the grass has been cut and is wilted, it can probably be fed in unlimited quantities, though even with some stock, which is exceptionally susceptible, care must be taken not to water immediately after eating.

A PARCEL POST ABSURDITY.

Editor Cultivator: I was glad to see the extract from the American Cultivator in your last issue. It does not tell the whole story, however. There is still the semi-official parcels post from Great Britain to the United States for packages up to eleven pounds weight. But there is also, and has been since April 1st of this year, an official parcels post for parcels up to four pounds, six ounces in weight.

You, Mr. Editor, can take a four-pound parcel to your nearest postoffice and mail it all the way to London, England, for 48 cents. If you want to mail the same parcel to your nearest town or village, you must pay 64 cents for the privilege. A payment of twelve cents a pound carries it all the way to London, but it costs sixteen cents to send the same package from Los Angeles to Pasadena, or San Francisco to Oakland.

When will American citizens ask Congress, why is this thus? Absurd? Yes, disgraceful and disgusting! Cultivate politics, ye farmers.—Edward Berwick, Pacific Grove, Cal.

ROUND VALLEY INDIAN RESERVATION.

The Cultivator is in receipt of several queries from interested subscribers as to the Round Valley Indian reservation in Mendocino county and as to details of its opening on October 3d. We can only refer such inquirers to U. S. Land Office, San Francisco, who can give more explicit information.

The report of the committee on hops of the New York Produce Exchange gives the United States crop for the year 1904 at 260,000 hundredweights, as compared with a crop for 1903 of 223,000 hundredweights. It also gives the European crop as 1,040,000 hundred weights, as compared with one of 1,140,000 hundred weights for 1903.—U. S. Crop Report.

The Onion and Its Culture

By J. C. Ostergard, Burbank, Cal.

Since prehistoric times man has cultivated this lowly, beloved and despised plant. From the lowliest hovel to the most magnificent palace home, it is openly despised, but covertly beloved. At any meal and at any season of the year, much as man affects to abhor it, he eats it.

Onions succeed best on a heavy loam with a slight admixture of clay, but not enough to bake and crack the soil. As to what variety is best suited for your locality, as the climate differs widely, it will be well to ascertain what kinds have been most successful in your neighborhood and act accordingly. In the mean time, make tests with other sorts on a small scale and be guided by results. We must not forget that what will prove highly profitable in one section of California, may not do at all in another. A patch of onions well tended often yields a profit so large as to make the successful orange grower scratch his head to the bleeding point. It is, however, the early spring crop that yields the largest returns. To get a spring crop, two methods are practiced. One is to sow the seed in drills; the other is to use onion sets. Each of these have their advantages. The sets will produce their crop when the price is high in the early spring, but the onion produced is lacking solidity, and only sells while no better ones are to be had. As soon as the onions grown from seed appear the profitable sales for those grown from sets is past. Could the ones grown from seed be put on the market a little earlier, the sale of those from sets would be all but impossible.

To this end, the so called new method may be employed with satisfactory results. This method is, however, not new, having been in practice in Australia for a long time and is there called the old method. Probably Solomon was right when he declared that there is nothing new under the sun. The method in the East is to sow the seed in hotbeds in drills at a distance of about four inches, using about twenty seed to the running inch, thinning to twelve to the inch. They are grown until they have formed bulbs about as large as a pea, or a little larger. Then they are ready for transplanting in the open. In Australia the method is the same, except that there the beds are made in a sunny, sheltered nook, such as can be produced by piling brush or boxes on the north side.

* * *

Method of Transplanting.—If the soil is not rich enough, stable manure should be applied at the roots for about twenty-five tons to the acre, or more if the soil is very poor; spread as evenly as possible, break up all lumps and harrow the field with a rapidly moving team, in order to thoroughly pulverize the manure. Irrigate well, plow and follow immediately with the harrow. Use an adjustable harrow, letting the teeth slant back at an angle of thirty degrees, or more, in order to fine the lower soil. Now furrow with a one-horse furrow to the desired depth and from twelve to fourteen inches apart. Have a boy go along and drop the young onions three to four inches apart, another following him up and firmly pressing the damp soil around the young plants. Be sure that the soil is damp. Considering that there is no misses and no danger of weeds gaining a headway, as is always the case where the seed is planted in drill, this method will prove as cheap as the old way of sowing in drills, and as the crop is surer, earlier and nearly twice as large, there is no reason why it should not supercede either planting seed in drill or onion sets.

It will require about one hundred and sixty-five thousand plants to an acre. These, if grown to weigh four ounces each, will yield over fourteen tons to the acre, or if a weight of eight ounces is obtained, nearly thirty tons. If your locality is too cold for open out of door hotbeds, use frames covered during the night with glass or canvas, or you may engage some one where it is warm enough to grow them for you.

* * *

DANDELIONS.

No plant for greens is so sought after as is the dandelion, yet in the many years I have frequented the markets here in Los Angeles I do not remember it ever being offered for sale. It is easily grown, will flourish in your lawn and make you think of old times when you see and taste it. Procure some seed, throw a little of it on your lawn and make a bed of the rest and you will be pleased.

* * *

Winter tomatoes, Yorkshire Hero peas and string beans may yet be planted in frostless sections. But don't be too hopeful regarding bean planting at this late date. The Broad Windsor excel all others, but it has no eatable pods, only the beans are used. Plant now turnips, carrots, cabbages, beets and kindred cool weather crops.

A SAUER KRAUT CITY.

Clyde, O., claims the distinction of making more sauer kraut than is manufactured at any other town in the world, including Germany. A single factory is that city has an output of 25,000 barrels for two months and a half. The magnitude of the business is realized in a statement that is made that 1800 acres of cabbage is annually utilized, and each acre yields ten tons, which brings from $6 to $7 a ton. The farmers in the city often receive $100,000 for their crop.

When the cabbages arrive at the factory late in autumn they are stored in receiving bins. Next the inspectors carefully look them over and then they go to a force of cleaners, where the cores are taken out with knives constructed for that purpose. From this department a continuance carrier brings them to the cutter, where they are reduced to slaw. One factory can grind 100 tons of cabbage in a day.

The cabbage goes from the cutters to the receiving tank, where salt is added, and from here it is put into 100-barrel vats. From these vats is is later transferred to the barrels, in which it goes to market.—Pacific Homestead.

THE PHENOMENAL BERRY.

The Phenomenal is the result of a cross between the Improved California Dewberry and the Cultivated Raspberry. It takes the color and flavor of the latter and size and shape of the former, described by Mr. Burbank as the largest berry ever before known, bright crimson raspberry color, productive, most delicious for pies, canning, jelly or jams.

The berries grow in clusters of from 5 to 10 or more and individual berries under favorable conditions, have measured three inches one way by three and one half to four the other. The vines grow as trailers. In field cultivation there are two methods:

One is to set the plants six or seven inches deep, six to eight feet apart in the rows, eight feet apart, let them grow one year but keep the ground well cultivated. Then set stakes twelve to sixteen feet apart and three and one-half to four the other. The vines grow as trailers. In field cultivation there are two methods:

One is to set the plants six or seven inches deep, six to eight feet apart in the rows, eight feet apart, let them grow one year, but keep the ground well cultivated. Then set stakes twelve to sixteen feet apart and three and one-half to four feet high. Stretch a wire from top of stakes and staple down. Then gather up the vines and loosely twine or tie to the wire and continue cultivation. The other method is similar, only the plants are set 12 to 16 feet apart in rows only 4 feet apart. The fruit ripens early and the largest yields are obtained on moist sandy loam soils.

After the fruit is gathered, go through and cut out all old vines and canes, as the new growth at the foot of the hill is the one to put up on the wire the following spring to bear fruit.—N. W. Horticulturist.

* * *

The Phenomenal raspberry so much resembles the Loganberry in appearance and flavor that it is practically impossible to tell one from the other. A California man who was sure that there was a distinct difference in flavor found himself in error when blindfolded in a test recently made at the exposition. We have not seen the Phenomenal plants growing and do not know whether they are as much like the Loganberry plants as the fruit of the two varieties. If there is as much resemblance in plants as in fruit, it is probable that many purchasers of Phenomenal plants have been supplied with the Loganberry plants. The Loganberry continues to grow in popularity in Oregon.—Oregon Agriculturist.

Mr. S. H. Taft of Santa Monica favors the office with samples of the Kadota fig and California Concord grape, which are exceptionally well flavored fruit, trees and plants of which he is introducing.

FEEDING BEES.

Editor Cultivator: Will you please tell me through the Cultivator what will be cheapest and bring the best results to feed my bees this winter, and about how much will twelve colonies require per week. They were transferred very late, have no stores whatever. Can they gather enough honey from now till the first rains to keep them alive, or shall I commence feeding them at once. They don't seem to be working much at present, but seem to cluster in a bunch near the top of the frames.—Subscriber, Watsonville.

The best feed for bees is made from dissolving best grade of granulated sugar in cold water. One gallon of water to ten pounds of sugar, mixed cold. If in large quantities, this may easiest be done by placing in the extractor say one hundred pounds of the sugar and pouring over ten gallons of water and agitating the extractor until all dissolves. It will require twenty-five to thirty pounds of this syrup for each colony. An old beekeeper tells us that it will be far better to give this entire feed at one time rather than to feed along as the bees need it. Where that is done there is danger of stimulating the bees to brood raising, thus increasing constantly the expense of the feeding. As to whether to begin feeding at once, you can best tell by examining conditions in your own vicinity. We imagine from what you wrote that it would be best to begin at once, however. One of the cheapest and, we are told, one of the best feeders, is to take old tin cans, melt the top off so as to have even surfaces around the top, fill with the sugar, place over the top a smooth board, invert instantly, which will bring the can upside down, but the suction will prevent the escape of the sugar, excepting as the bees draw it from under the tin. Mr. Clayton, of the Medary Supply House, tells us he has seen one hundred colonies of bees take up a ton of sugar in one day through these home-made feeders. Glass fruit jars and other receptacles may also be used.

THE EVAPORATION FACILITIES OF A BEE HIVE.

The means of evaporation which the bees have within the hive are wonderful to contemplate. During the honey flow they go out and bring in the nectar, which at its best is apparently but little better than sweetened water, and evaporate the water out until we have the delicious honey which we eat on our cakes or hot biscuit. During the height of the honey flow we have often set a colony upon a scale and weighed them at night and morning. Often we have noticed that they have increased their weight ten pounds during the day, and that in the morning they weighed two pounds less than they did in the evening. What was the matter, robbers, or did they eat the honey up? Oh, no, they have simply evaporated two pounds of water out of the honey in the hives. Did you ever notice early of a warm evening when honey was coming in rapidly several bees standing well upon their legs and making their wings go so fast that you could not see them? The workers coming in from the field loaded with nectar are passing under the bees who are using their wings so rapidly. These bees are getting up a circulation of air through the hive and this is taken up by other bees and carried along by other bees at regular intervals while others seem to be exposing this nectar to the circulating air with their tongues. What a humming there is going on within the hive? If the weather is warm enough this is carried on all night. Hold your hand down close to the entrance. What a draft of air there is passing through the hive; on one side the air is cool and on the other it is warm. When we state that they carry in the sweet juices from the sugar corn or sorghum and evaporate them down to a consistency with which they will keep we are able to give you a vague idea of the wonderful evaporating facilities there is within a bee hive.

Practical Advice on Parasitism.

This is the time of the year when the last brood (for the season) of the wooly aphis commences to infest the trunk, branches and entire top of the apple trees in this locality. Generally speaking, apple growers have very little idea of the destructiveness of this late brood and of its disastrous effect upon the apple crop of the coming year. Upon the older trees the aphis seem to prefer the fruit spurs, congregating in large masses at the base of the fruit buds that, under more favorable conditions, would develop into a source of profit the following season. The result of the punctures of these myriads of little beaks, is a distorted appearance of the spurs, a mis-appropriation of the vital forces of the tree, a weakened and, in many instances, destroyed condition of the fruit buds. Especially is this true of the White Winter Pearmain. Another important factor is that it is generally this late brood that develops the perfect, winged, sexed form of this insect, some of which fly away and by depositing their winter eggs upon other trees start the nuclei for new colonies.

In the apple orchards of this district these later broods of wooly aphis are completely destroyed by the native parasites. The various forms of the native lady beetles, the Sryphus flies, the aphis lions and principally by a little known parasite, a chalcid, probably Aphelinus mali.

While this control by natural methods is invariably complete at this season of the year, a large amount of damage is done by these pests before relief arrives and the object of this article is to advise the growers how in a great measure they may circumvent this by a little prompt action on their part. A small fraction of the energy and expense necessary to rigging up and spraying the orchard devoted to collecting and distributing these beneficial insects at the first appearance of the aphis will produce as good, if not better results.

There are four forms of the red, or red and black-spotted lady beetles common to this locality. Without going into detail, any and all of these are valuable for this purpose. They may be found upon the corn and pumpkins, and upon the weeds along the ditch banks in large numbers. A simple way to collect them in this instance is to take a dust pan and a small sized fruit jar. Holding the pan in one hand, bend the cornstalk or weed over the pan and give it a quick, strong jar. This will cause the lady beetles to fall into the pan, from which they can be quickly and easily emptied into the fruit jar. They should be liberated in the center of the orchard late in the afternoon and once there they may be depended upon to control the aphis without any further effort on the part of the grower.—Fred'k Maskew.

Outlook for Citrus Industry

We referred last week to the period of the year and to locality as a factor in securing satisfactory prices for different varieties of citrus fruits and we take up this week another factor of the marketing which is of vital importance, perhaps far more so to the grower than that of the period of the year or locality.

There are four different channels of disposal of citrus fruit. The one through which the largest amount passes is a co-operative movement which has attracted attention of producers the world over, for it is the largest and most successful of its kind in existence. This is what has been known as the Southern California Fruit Exchange, but, beginning with this year, takes its new name of the California Fruit Growers Exchange. The next strongest factor in the marketing of citrus fruit is a group of growers and shippers known as the "Independents." Following them comes the California Citrus Union, a collection of seven of the largest shipping firms sending fruit from this section. At least they were by far the largest factor in the fruit market until within a very short time. Now, as compared with the total, they are secondary to the Independents. Last, and an exceedingly small factor in disposal of the total crop is the "local shipments," disposal of culls and ordinary stock to peddlers and other factors which pertain only to the Coast. These may possibly be properly grouped with the Independents, but in any case are an exceedingly small factor compared to the whole.

* * *

The California Fruit Growers' Exchange shipped during the past year approximately one half of the output of the State, or, to be more exact, slightly in excess of forty-eight per cent. This organization is a purely co operative body of growers, bound together for the purpose of marketing their fruit with the least possible expense and securing the best possible price. It has been dubbed a trust, but is not such in any sense whatever, for there has never been any effort to put exorbitant prices upon the product of its members, but simply to so manage affairs as to secure the best possiblo transportation facilities and best distribution of the fruit.

There are three wheels to the organization, the first being the central, or California Fruit Growers' Exchange, an incorporated body whose stockholders are made up of representatives from fourteen district exchanges. These district exchanges in turn are corporate bodies, whose stockholders are representatives of the local association of growers. The Growers' Association sometimes contains several hundred members and in one or two cases only one person forms the entire membership, where such grower has an exceedingly large amount of fruit and controls his own packing house. These associations have to do with the gathering into the packing house from the orchards of the fruit, packing, placing in cars and delivering bill of lading to the district exchange. This district exchange is the business factor, at least to the extent of choosing its market with certain limitations, collecting the fruit from the California Fruit Growers' Exchange and turning same over to the association management. This district exchange has control, also of the price which it may take for the fruit, diversion of cars, etc. The California Fruit Growers' Exchange has the employment of a corps of agents who are scattered in the various markets of the East, develop new markets and in a general way look after the interests of all California growers, especially as to freight rates, icing charges, tariff, reciprocity tinkering, or any other factor which will affect the industry. In the point of freight rate on lemons alone, the Exchange has accomplished a great service for all lemon growers. These are points which are seldom considered by many growers who are not members of the Exchange and there are, without question, obligations to this organization which "outside" growers should not be slow to recognize.

* * *

The next strongest factor in the marketing, as we have said, is the independent group of shippers and growers. This, until the last year or two, has been of no great importance in the citrus trade. But, since the disruption of the California Fruit Agency, there has been a breaking away from alliance with shippers forming the Citrus Union. At the time of the Union of these two large bodies, that is, the Citrus Union and the Exchange, the Union controlled very nearly half of the output of the State. Now, it has been claimed that its output during the last season has been reduced to very nearly sixteen per cent of the total.

This would leave approximately thirty-five per cent of the fruit which has passed through independent hands. These independents are sometimes fruit brokers or buyers who do not affiliate with the Exchange, neither with the Citrus Union, also associations handling their own fruit as they see fit and sending to any market they desire. Within this body there are a few assoications of growers co-operating in handling their own fruit. Some of the most successful being in Redlands. These associations not only attend to the gathering of the fruit from the orchards, packing, loading and shipping, but also to their own marketing, entirely. There have also been other associations at Highlands and at Riverside, though, as a rule, in those places the independent marketing is done through buyers, shippers, or brokers dealing with the grower.

The Citrus Union, as we said, at one time controlled nearly one-half of the output, but, owing to the breaking away of many adherents to its plan of marketing, is today very materially reduced. The plan of marketing is: The Union makes a charge of thirty-nine and a half cents per box for packing and marketing charge, save the brokerage and auction charges, which are additional. Then, with the agents in the East, they secure the best possible price for the fruit and turn balance over to the grower. We believe there is in this organization a certain feature of pooling by which the fruit of the various shippers through this organization is pooled from time to time, when they desire. The various firms comprising the Union are, to a certain extent, independent in their handling, but in the marketing at the eastern end work together for the purpose of reducing expense and to better control the market.

All of these methods of fruit handling have certain variations at the eastern end of the line. That is, all of the different shippers make an effort to secure f. o. b. sales. While in general the Exchange has had a system of "selling delivered," it has not during the past season refused any reasonable f. o. b. order, but the old "f. o. b. inspection allowed" plan is decidedly tabooed. The theory of the "selling delivered" adherents is that "f. o. b.-inspection-allowed" plan allowed the buyer on a declining market to claim decay and poor grade as well as other and often untrue claims as a reason for his turning down his f. o. b. order, then securing it at his own price or turning it upon the market where it is sold for whatever it will bring.

This abuse became so flagrant that the Exchange decided it would sell delivered at the eastern market for whatever the market was at that time, thus securing the benefit of any rise in price after the fruit was shipped which would in turn compensate for the losses which always occur when there is a slump, whether f. o. b., selling delivered or no matter what plan.

The claim has been made that absolutely f. o. b. sales could be made at this end if all would join in the plan. This may or may not be true and the question is not worthy of discussion, from the simple fact that it is absolutely impossible to get the citrus growers or any other growers to unite and stay united on any one plan. From the very necessity of the case, there will always be an element which will refuse to join with any one plan and a plan of marketing which takes into consideration a combination of all will certainly fail. There is, however, a rumor that an effort is to be made to establish a large auction house in California, and attract customers to the fruit instead of sending the fruit for the customers.

Both the Citrus Union and the Independents have also made f. o. b. sales, the Union especially making strong ef-

fort to put its business upon that basis. But we do not believe a single factor of any importance in the citrus trade has been able to dispose of all its product in that manner and while in some quarters the "selling delivered" plan has been condemned, yet all have engaged in it in some form or other during the past season. This has been dubbed as the plan of sending fruit into the market and taking whatever the buyer saw fit to pay for it, but, with some allowance for business management and proper distribution, it may be said that that is all any fruit will bring in any market.

Of course, in most of the markets of the country the selling is done through brokers, sales agents, or possibly direct to large houses dealing with the central body. In addition to this, in the larger cities the fruit is thrown into fruit auctions. This has been strongly condemned, as well as the "selling delivered" plan, but, as it is followed by all the organizations shipping fruit out of California, we assume that it is fairly acceptable in its results to all. As a matter of fact, the prices secured in the auctions are only slightly under those secured in other markets. When it is remembered that, as a rule, the quality of the fruit going to the auction markets is very naturally below that going to the other markets, it appeals to one who looks at all sides of the question as if the auction markets were not to be condemned. The fruit going to the auction market is of a lower grade in general, not only because of choice often in selecting the fruit for such markets, but in addition because of the fact that the fruit which has been rejected or unable to find market in other sections, after several days en route is finally diverted to the auction and there forced into the market for what it will bring.

As to local sales a strong stand has been taken during the past year or more by some growers and associations to stop the sale in nearby markets, and even San Francisco, of culls and other low grade fruit, which is not worth the shipping to eastern markets. There are hundreds of tons of such oranges in San Francisco and Los Angeles markets which in the eyes of some are called for, that the poorer class of people may have some of this delicious fruit. But this, as well as the better grade of fruit, by the time it gets to the hands of the poorer people, often costs as much as a fairly good grade of fruit. In case of scarcity of output, it is perhaps wise for the grower to get all he can for all grades of fruit, but in a season like the past when good fruit was shipped east only to pay transportation and charges, to bring absolutely nothing to the grower, it would have certainly been far wiser to have sold such fruit in California markets and pay the high freight to the East only on higher grades of fruit. The time will probably come when this waste product of the citrus orchards will be taken up in the manufacture of marmalades, candied peel, citric acid and other products, which will not only remove the fruit from the market, but, at a vastly higher value, will bring additional returns to California labor and add to the greater prosperity of the State rather than take from it, as is now often done.

* * *

Some prices received this year in different sections will be touched up on next week with extracts from some reports of associations will be a feature another week. Also amounts shipped from the different sections.

CITRUS FRUITS

By C. A. Day. Pasadena

AN OUNCE OF PREVENTION.

I wish to call the attention of our citrus fruit growers to the importance of establishing and maintaining an effective quarantine against insect pests. Large sums of money are being expended every year by citrus fruit growers to control the scale and other pests that have been originally imported into our State from some foreign section. In every case the first and original infection was a small affair, where, if proper precaution had been taken, there would have been no original introduction; or if when first discovered, prompt measures had been taken the infection would have been stamped out at a very small expense by the destruction of the infected nursery stock, plants or fruit. The introduction of scale and other pernicious insects have been invariably by the means of nursery stock and fruit. The red, purple, black and other scale have been brought to California in this way, and after becoming located in a single section and having gained a permanent foothold, they have been allowed to spread from orchard to orchard and from section to section, until at the present time some species have become widely spread throughout the citrus sections of the State.

Learning from past experience, we are today maintaining, through State and County horticultural commissions, a fairly effective quarantine against the introduction of foreign insect pests. The State Commission of Horticulture maintains a quarantine at the ports of entry on our seaboard and the county commissioners of horticulture are doing a no less important work in quarantining against the shipments of nursery stock and fruit from Florida and Mexico.

* * *

New Pests Bronght In.—To show the importance of eternal vigilance on the part of those connected with the horticultural commissions in guarding against the introduction of new dangers into our State, I will give an instance or two that have come to my personal notice.

A little less than a year ago, Oonshiu oranges shipped from Japan were found at the fruit stands in the cities of Los Angeles and Pasadena, infected with two species of scale new to California. The fruit was promptly destroyed and investigation showed that this shipment had come through San Francisco, and the State Commission had fumigated the fruit in the boxes, and as the fruit was wrapped in paper the fumigation failed to destroy the scale and the eggs. This experience of the State Commission will probably prevent a recurrence of a similar instance. Two years ago a potted plant enclosed in a small box was brought by a passenger on a steamer from Japan and was left with a nurseryman of Pasadena to be treated for three varieties of scale which infested the plant. The plant was probably brought through in the stateroom and smuggled ashore covered with wraps.

Within the last year several shipments of plants and nursery stock from Florida have been destroyed by the horticultural commission at Los Angeles and Pasadena. Two of these shipments were badly infested with scale and white fly. One of these shipments, which I personally inspected, was infested with live purple scale and the white fly in the scale stage. Two shipments of plants from Florida, coming by mail, were already planted out before they came to the notice of the commission. Some time ago a shipment of native shrubs and trees taken out of the woods of Eastern Massachusetts arrived in Pasadena. This shipment came from the section where the gypsy moth is well established.

The above instances show the danger which continually threatens our State. Many people do not seem to recognize the danger of importing insect pests into the State, and when they cannot get the stuff through by freight or express will attempt to get it through the mail. There is a ruling of the United States Postoffice Department which gives the postmasters the right to notify the horticultural commission of the arrival of plants by mail. This is now being taken advantage of by the commissions to hold up shipments from Florida and the Gulf States. There is no doubt but that shipments of plants and nursery stock sometimes arrive and escape inspection by the commissions.

Strenuous efforts are being made to prevent the introduction into the State of the white fly of Florida, the orange worm of Mexico and new species of scale from the Oriental countries. In these cases and all similar ones the ounce of prevention will be very much cheaper than the pound of cure.

* * *

LOCAL QUARANTINE.

In certain sections of the State there are local infections of pernicious insects, while other sections are free from similar infections. The horticultural commissions of the various counties are doing good work in checking the spread of certain insects. It is important to maintain a local quarantine against the spread and wide distribution of these local infections.

* * *

Local Infection.—Very frequently red scale is introduced on to a place by the planting of infected rose bushes, or ornamental shrubs and trees. In planting out a young citrus orchard the owner sometimes plants trees infected with black scale; the result of this is to establish a stock of scale that quickly stocks up the young, vigorous growing trees and will make it necessary to go to the expense of treating the trees at the end of the first year. If the trees planted had been absolutely clean the orchard would not have required treatment for two or three years, according to its location near or remote from badly infected orchards. Clean trees cost no more than those that are infected. It only requires necessary precaution on the part of the purchaser to avoid the early expense of spraying or fumigation.

The planting on the street adjoining an orchard of camphor and other trees subject to scale infection, is not good policy. When once infected it is impossible to effectually treat the street trees, especially after they have attained any great size.

* * *

NON-RESIDENT PROPERTY

Is very frequently the breeding ground for scale, which come to infect adjoining orchards. In such a case it is along the line of prevention to request the county horticultural commission to force a clean up of such orchards in order to protect the other orchards of the neighborhood.

* * *

PICKING.

Picking sacks and boxes are a source of infection for red scale, and the members of every association should demand that all orchards of the association should be cleaned from scale.

* * *

THE GROWERS SHOULD CO-OPERATE.

With each other and the horticultural commission in securing a neighborhood clean up. In case one orchard is cleaned and an adjoining orchard not treated at all the treated orchard is soon reinfected from the other. Where there is a slight infection of red scale in an orchard it is economy to fumigate so effectually as to eradicate the scale and prevent the infection of the entire orchard.

Prevention along the lines suggestew above will in the end make a great saving of future expense to the orchardist and will insure more fruit and better fruit.

GOOD GARDENS NOT COSTLY.

Too many people of moderate means hesitate to make a flower garden because of the impression that "it costs too much." This is not so. You may purchase for fifty cents enough seeds to give you a fine start with from five to ten sorts of flowering perennials. Every year your plants will increase in size and these may be divided every three years until your garden is fairly overcrowded with a wealth of plants and blossoms. As stated in our last issue, this class of plants make a wonderful system of roots and are very drought-resistant. After becoming well established these plants need only an occasional irrigation to give splendid results. It is indeed a poor farmer who cannot afford a garden of the cost above noted and the flowers so grown will efface that bare, inhospitable appearance which too many farm dooryards present. Somehow a farm house surrounded with bright flowers bespeaks both hospitality and prosperity and add materially to a general home-like effect. Passersby hesitate to even ask for a drink of water where there is a barren dooryard, filled with rubbish and broken farm implements. The appearance of the yard is generally an index to the character of the inmates. Let us have flowers everywhere and as many as possible.

* * *

RURAL IMPROVEMENT.

The man in the country who improves his home surroundings not only benefits himself but the entire community in which he dwellls. Good examples are catching, like the measles, and when such a man forces the contrast between the looks of a place well cared for and his neighbor's uncared for, it becomes a great and effective object lesson. Try it and see. The cause of the improvement of home surroundings is to be congratulated that the press takes such a practical view of this great question, and lends its powerful voice to promoting its objects. It is mainly through such mediums that the farming communities can be reached, and it should be a constant effort of the improvement associations to keep the rural press posted on the progress of the movement, and to supply them with interesting and instructive practical matter for their columns. It should be an easy matter to impress upon the farmer the advisability of improving his home and its surroundings. The very appearance of the house and grounds of any farm affects the value of the farm in a far greater degree than is realized, and the towns or villages which nestle in the midst of agricultural districts would also be materially benefited by the interest which would be aroused from the surrounding beauty spots which improved farm houses would provide. There is such an uplifting tendency in beautiful environment that, given a hearty effort to impart and encourage the educational influences necessary to bring about reform, we shall soon witness the effects.

* * *

VILLAGE IMPROVEMENT.

The cities, great and small are doing their whole duty in providing parks, but the villages and small towns seem to think that parks are luxuries beyond them. We hear political economists bewailing the fact that the cities are growing faster than the country, and they ask why it is. Parks, boulevards, libraries, added to the other attractions of the cities are sure to entice the country youth from the humdrum life in a frowsy hamlet. And who can blame them?

But if Mr. Carnegie, or Mr. Rockefeller, or other of our rich men should assist and encourage our country towns to build parks, to plant trees and beautify their towns, thus making their homes pleasant, the glamour of the city would not be so striking. The building and endowing of great libraries is most commendable, but there are many things we need more. Those fine palaces filled with books are handsome monuments to the rich donor, but the same amount of money expended in playgrounds about the city schools and in parks in country village would bring more health and happiness to all the people. Our country people need to be educated along this line. Make the country towns more beautiful, and the desire to leave them for the great cities will not be so great. In spring time the dwellers in the cities turn with longing to the country and the country town. They long for green fields and singing birds, and happy the suburban town whose people have made its streets shady, its appearance attractive, for to such will come people who add to the community's life and prosperity. From an economic view, village improvement pays. It fills up vacant houses, it increases the value of your property, it educates your boy and girl, and it will make this world a pleasanter place than you found it.

* * *

HERBACEOUS PERENNIALS

Most of these plans will grow where any plants will. Good garden soil, warm and light, rather than cold and heavy, is preferable. They do not do well in wet undrained soil. Fine manure, carefully forked in each spring, pays in better plants and more flowers. In setting plants, break up and mellow the soil for a spade's depth. Fill the hole, which is half deeper than roots are long, with water. Set the plant in, spread the roots well so that none will remain in a dense mass. Work the soil well in among them, taking care that no hollow places are left. Press the soil firmly in against the roots. Cover with fine rich dirt on top; or better still, with well-rotted manure; water thoroughly. The weeds should be kept down and the soil stirred enough to keep the surface dirt light and open. As the flowers pass their prime the flowering stems should be cut away, not as a matter of neatness, but to prevent the plant from exhausting itself in prefecting seeds. If seeds are wanted, leave a sufficient number of stems.

* * *

GROW HERBACEOUS PERENNIALS

1. **For Their Beauty**—Great variety in the habit of the plant. Much diversity and beauty of foliage with flowers of interminable variety in form and color. By-a proper selection, a continuous bloom can be kept up during the entire season.

2. **For Their Permanence.**—When the foliage and flowers fade, that is not the last of them, they will appear stronger and more beauteous the next season.

3. **For Their Dividends.**—One can give away the increase and still be as rich as he was before. At the same time he can do good to his neighbors and friends by adding to their enjoyment.

4. **For Their Ease of Culture.**—When once plalnted they may usually be left undivided for three or four years. and in some cases much longer, requiring little or no care.

5. **For Their Flowers.**—They are generally abundant bloomers, and many are excellent for cut flowers.

6. **For Their Cheapness.**—This class of plants cost very little when obtained in small size. Better perhaps, than buying plants, is growing them from seeds; it is an easy matter.

* * *

HARDINESS OF EUCALYPTS.

Mr. W. Vortriede, of Stockton, reports the following eucalypts as growing on the State hospital grounds in that city. He also states that some have at times been injured by frost—one night in 1898 the thermometer registered 17 degrees.

Eucalyptus globulus, circumference, 9 ft., 3 in.: height, 110 ft.; E. tereticornis, circumference 7 ft., 2 in.; height 90 ft.; E. rostrata. circumference, 5 ft., 3 in.; height, 70 ft.; E. goniocalyx, circumference, 6 ft.; height, 50 ft.; E. macroryncha, circumference, 3 ft., 2 in.; height, 35 ft.; E. viminalis. circumference, 6 ft., 5 in.; height 85 ft.; E. paniculata circumference, 6 ft., 10 in.; height 115 ft.

As Mr. Vortriede is known to the writer as a reliable man and an excellent, well posted gardener, we have no hesitancy in recommending the above species for the San Joaquin and Sacramento valleys, except in the colder parts. It must be remembered, however, that the older a tree grows the more immune it becomes. Young trees of the above species are liable to be injured every winter.

WALNUTS IN FRANCE.

The present outlook for this season's walnut crop is not flattering. Owing to the warm and dry weather, the nuts have fallen from the trees in such quantities as to seriously alarm the growers. Even should cooler weather prevail, with sufficient rain during the balance of the growing season, the crop will fall below that of last year. The records show that in the year 1904 there was a total export to the U. S. of 2,930,000 kilos (a kilogram is 2 1-5 lbs.) of walnuts, of which 380,000 were shelled walnuts, and 2,250,000 kilos of walnuts in the shell, valued at $696,768. It is impossible to quote prices now, but hope later on to report fully in regard to this matter.—From report of D. J. Murphy, American Consul at Bordeaux.

WHEAT, rye, oats and barley are dependent on POTASH for proper nourishment to produce full, heavy kernels of fine milling quality, and strong stalks which do not lodge.

A complete fertilizer, containing not less than 6 per cent. of actual POTASH, is best for grain. A larger amount may be frequently used with added profit.

Our books on agriculture will be sent free to all farmers who write for them.

General Agricultural Notes

THE PANAMA CANAL VS. DITCHES

The Panama canal is conceded to be the giant undertaking of the age, a project upon which the French have failed, the United States will now take hold and build. We will construct the Panama canal beyond peradventure of a doubt and it will become the greatest and most important waterway in the world, with untold possibilities to commerce and the strategy of possible warfare. What will it cost and when will it be completed? Engineers predict in 12 or 15 years and estimate an expenditure of 200 million dollars. Yet it will be observed that the wording of these estimates is provisional and qualified both as to the amount of treasure necessary for the work and as to the time of completion.

But while this great American work is going on, or rather its preliminary surveys and excavations, Uncle Sam is doing another engineering work which promises even greater results than the Panama canal. The truth of this becomes manifest to the most unthinking upon a little reflection. The government has now under consideration —one is already established—seven great irrigation projects in the West involving the reclamation of some million and a quarter acres of desert land, at a cost of about 30 million dollars. A half dozen more are in the course of survey and commencement of work.

The fund for this work is constantly growing from the receipts of all the sales of public lands; moreover, as every dollar expended by the government must be returned to the fund by the settlers taking the land, the fund becomes a revolving one and is capable of use over and over again for building new works.

It is officially estimated that there are over 70 million acres of irrigable land in the West and it is admitted that an intensively cultivated, irrigated, agricultural community will support a population of one person to the acre, which would people the western half of the United tSates with nearly the present population of the entire country.

The cost of this great work would amount to two billion dollars—a work the vastest even entered into by any country in any time, yet costing the government not one dollar, for every dam and every canal constructed is paid for by eager settlers who flock upon the rich, irrigated desert lands. —Guy Elliott Mitchell.

STORING POTATOES.

The easiest way to store potatoes is to pile in ricks on the ground and make roofs of boards. By this method there is usually good ventilation, compared to depth of pile, and it can be kept dark, and nearly at the temperature of the soil.

When stored in the cellar the very important things are, ventilation and exclusion from light.

Some good suggestions, applicable to any locality, are given in a recent number of the Prairie Farmer:

Instead of piling the potatoes against the wall or on the floor, slats should be nailed a little apart, about six inches or more from the wall. This will give a circulation of air behind the pile. A temporary floor should be put down with cracks between the boards. This will permit air to circulate under and through the pile. Then if the piles have to be made very large, square ventilators of wood, made of slats and running from the top to the bottom of the pile, could be put in here and there through the pile. These with the ventilation afforded at the sides and the bottom will keep the potatoes in much better condition than if they were in a solid pile.

Another good plan is to keep the potatoes in large crates made with slats close enough together to prevent the potatoes getting out. The ventilation between these crates would assist very much in keeping the tubers in good condition. Thousands of bushels of potatoes are lost every year when there is disease in the crop by neglecting ventilation. The temperature of the cellar or storehouse should be kept as nearly 33 degrees to 35 degrees F. as possible. The cooler potatoes are kept without freezing the better.

Not only is the value of the tubers for seed greatly lessened by sprouting, but they are also much injured for eating. Moreover, if the potatoes are held over to sell in the spring, there will be a great deal of shrinkage in weight if potatoes are allowed to sprout. It is important to have some means of letting cool air into the cellar towards spring when it is difficult to keep potatoes from sprouting. The cool air should be let in at night when the temperature is lowest and the cellar kept closed during the day.

Sometimes it is difficult to get all the crop to the cellar at digging time and when this is the case they may be put in piles of forty bushels and covered with straw, a little earth on top to keep them dry, more earth being put over the straw, if the weather becomes cold.

SOMETHING ABOUT FORMALIN.

Farmers have often asked the questions: "Must the solution which is made up for treating seed grain all be used up the same day?" "Will it grow weaker from standing?" "Must a new lot of solution be made each day?" "Does the standard formaldeheyde lose strength if left uncorked?"

We have thought it worth while to make some special tests of this matter of evaporation and the results are a surprise.

We have boiled formaldeheyde of many strengths and tested both that which evaporated and that which remained in the still; and we have made similar tests after slow evaporation at ordinary temperature. The results are always the same. Solutions of formaldeheyde grow stronger by evaporation; that is, water is given off faster than formaldeheyde.

This is an important fact. The farmer can therefore rely on a solution which has stood open for a number of days being fully as strong as when first made.

It also gives us a pointer in regard to weakening or adulteration. Solutions of standard formaldeheyde do not grow weaker from long standing unless water is allowed to get into the bottle or carboy. This also settles the complaint of the druggists that "farmers who fail with smut treatment do so because they carelessly allow the formaldeheyde to lose its strength by evaporation." And finally, it shows that the manufacturers of formaldeheyde who contend that it is difficult to make water hold 40 per cent have not, perhaps, tried as hard as they might. Full details of this work will be given in the Annual Report of the Experimennt Station for 1904—North Dakota Experiment Station Bulletin.

Exportation from the Philippine Islands of the dried kernel of the cocoanue, known as copra, is shown by the recent Philippine census to be steadily increasing and promises to become of great commercial importance. The value of the exports of copra and cocoanuts for 1902 was $2,701,783.

IT'S PENNY WISE

Policy to set out a good tree, costing good money and then let the sun burn the bark, or the rabbits gnaw it when for $1.00 an acre you can get Yucca Tree Protectors that are practically indestructible. Write for free sample of the wrap. Yucca Mfg. Co., 2124 Willow St., Los Angeles.

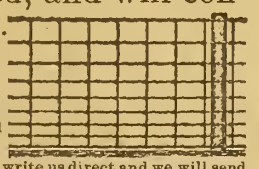
AMERICAN FENCE TALKS
By the Makers

There are many fences on the market. Some tell of their wonderfully hard wire; others speak of new form of construction that make all other forms look ancient and worthless. But through all this it remains a fact that more miles of American fence are in use than of all others combined, and will continue so.



American fence is for sale by the dealer in your town. You can find it there, examine the different styles and make a selection to suit your requirements. Or, write us direct and we will send you a catalogue and tell you where you can get the fence.

The Practical Educator.—The San Francisco Chronicle makes the following observation in reference to one of the newer men in public agricultural work in California:

"P. H. Dorsett, who is in charge of the national plant gardens at Chico, is reported by all who know him and his work to be the right man in the right place. Doubtless, he is a "theorist," but, in addition, he is said to possess the merit of being an all-round and remarkably successful "practical" farmer who can make anything grow where it can be made to grow at all."

It is a happy combination where education and practical knowledge obtain in one man. It is fortunate, in the best sense, to find such an one for the experimental stations of California. Those are the men needed today in our public agricultural stations.

It should be remembered that the education that counts is the one which teaches how to do the practical things, those things for which there is a demand. The age demands a thorough knowledge of the things necessary to bring results.

Our agricultural schools and colleges ought to turn out not only scientific men and women, but practical operators as well, for the need of the world is for the dual purpose teacher, the man who knows, and can put his knowledge to practical account.

Farmers' Unions.—Every now and then we hear of farmers going into "unions" to better their condition. The thought takes the form of an epidemic, sweeps over a district more or less broad, as the case may be, and then dies out.

The last case which has come under our observation is that alleged to exist in Wisconsin and Minnesota, where the union spirit is reported to have taken possession of the country people to the extent of their uniting with the Chicago labor unions.

For the life of us we can not discover where the farmers of these States, or any other, can be benefited by uniting with the American Federation of Labor, the name by which the unions in Chicago are known. We might see, and indeed we do, where the farmers would be benefited by a co-operative association for mutual protection in many ways, but the idea of a farmer submitting to the dictates of walking bosses who would tell him how to run his business is of all things most absurd. In the first place no one can tell a farmer how to manage his farm, it is a proposition which he alone must work out, depending as it does upon so many different conditions. In the second place we doubt if he could be fooled into believing, for any great length of time, in the virtue of heeding the mandates of a boss, or of paying dues into a treasury which would go to support a worthless lot of vagabonds known in genteel terms as "walking bosses." We remember when this spirit of unionizing took possession of the farmer politicians of some of the States of the Middle West. It lasted just long enough for a few shrewd fellows to get fat jobs in county and State politics, and then the farmers got wise and abandoned the enterprise. The rule is, that farmers, as a class, are too intelligent, too self reliant, too independent to ally themselves with any union, the only purpose of which is to line the pockets of walking bosses and loafers. The average tiller of the soil has no use for trades unions nor for trades unionists. Farmers as a rule attend to their own business, work steadily, live frugally though comfortably, obey the laws of the land, respect the flag of their country, and discharge their duties as citizens. They would be out of harmony with unions made up of men whose interests are in no way concerned with theirs. If the farmers could unite on a plan which would be broad enough to protect their interests against the combines formed to farm the farmer, as was and is the case with the beef trust, they would have a union which would benefit them, but to transform them into trades unionists would be foreign to their calling and last only long enough to open their eyes to the fact that somebody is working them for support, at the same time depriving them of their right to hire whoever they please to assist them in their work, and to discharge whoever they may wish for whatever cause they may see proper.

Fortunately for the country, the farmer always has had independence and good sense, and it will be a long time before the mass of the tillers of the soil will surrender these to the dictation of any trades unions, or anything else.

* * *

Only a Beginning.—The plea of guilty entered by four officials of the meat packing firm of Schwarzschild & Sulzberger Co., in Chicago last week, followed by a fine of $25,000 imposed by the Court, is only the opening chapter of a series of convictions which will follow one another, as rapidly as the guilty packers' cases can be reached in the Federal Court. For a series of years this packers' combine, which includes every packing plant from Chicago to the Coast, has been accumulating wealth to an astonishing degree by first robbing the producers of beef and pork, and then holding up the railroads for rebates. So vast has become the capital of the combine that it was feared no law is in existence which is strong enough to clinch the illegal operators of the scheme and secondly, that the government would not be able to secure legal talent of sufficient calibre to cope with the cotrie of eminent counsel retained by the defendant corporations, for it must be remembered that not only are the packers in the toils, but the railroads as well, they having granted the illegal rebates demanded by the packers. It is well known that the railroads of the country employ the very ablest lawyers to be found in the United States, and against them will be placed the government attorneys, usually a class whose legal abilities are good, but not the best, because the salary of $4500 which the district attorney receives as his annual compensation, is not sufficient to warrant the brightest lawyers, as a general thing, tying themselves down to government business alone. But the President has determined to break up the beef combine and to do this he will summon the fullest energy of the government and bring to its support the strongest legal ability he can find, which he can obtain. The law may be defective in some essentials, but it is apparently clear enough to cause the packers sufficient uneasiness to hasten to throw themselves upon the mercy of the court, as was done last week in Chicago.

The stockmen throughout the United States have reason to be glad that at last the end of the packers highway robbery scheme is in sight.

* * *

Advertising Does Pay.—The other day a patron of the Cultivator telephoned the business office this message: "Stop my ad. I am sold out." Then followed the voluntary suggestion, "I have had the best results from advertising in the Cultivator of any agricultural paper I have used." Now this was saying a good deal, for there are several newspapers in the State of the general character of the Cultivator, and this advertiser has tried about all of them. To say he has had the best success from his advertisement in the Cultivator, of any paper he has used, is certainly a compliment to the Cultivator, as well as to its intelligent readers who, each week, reach an average of 20,000 or more.

Barnum, the "greatest showman on earth," as he used to call himself, always contended that he got the best results from advertising in the highest class of papers, hence his advertising managers and agents, always put in their showiest cuts and announcements in the religious papers, where they could get in. The Independent, the New York Advocate, the Pittsburg Christian Advocate, and other great religious papers, were always sought as mediums by this live and humming showman, whose spirit of vivacity and vim made the whole world his friend—and him a millionaire. He realized the power of the high class journal to forward his enterprise. The Cultivator is a growing proposition in California, it is pushing into new territory each month. It is adding to its clientage men and women of character, intelligence and push. They read the advertising columns of the Cultivator for what they want to buy along agricultural lines, and they tell us that almost always they find goods as represented.

This speaks well for the reliablity of our advertisers and for the close discrimination used in admitting advertisements. Naturally, sometimes an advertisement will go in the paper where facts subsequently develop that it is unreliable. But this seldom occurs and such advertisement is taken out as soon as the facts are discovered. The Cultivator is exceptionally a fine medium for reaching the farming public, and more and more will this prove true as the paper extends its acquaintance and brings to its support the wide-awake new citizens of the State.

* * *

Rockefeller's Prediction.—The other day the telegraph reported John D. Rockefeller, in an interview with W. H. Moore, president of the Good Roads Association of the United States, as saying, that in 1907 and 1908 this country is going to experience a "hard times crisis."

Now, in the first place, it is to be doubted if Mr. Rockefeller ever made the prediction, but if he did, he certainly had a motive for so doing. He is either seeking to create a "hard times panic," in which case Standard Oil would profit immeasurably by a slump in the general market, or he is mad at Mr. Roosevelt because of his attitude on trusts and combines and wishes to bring on hard times out of revenge.

It is unreasonable to suppose, however, that a man of Mr. Rockefeller's experience would make any such statement. His interests are too general and diversified. But allowing that he made the prediction, where is the basis for it? At present it does not appear. The general business situation is satisfactory. The railroads report a greater volume of business than they can handle. Large orders for steel rails, for locomotives and freight cars have been placed in the car works of the country, which will take two years to turn out. The crop statistics are satisfactory and no special discontent exists between labor and capital. So, all around, conditions are good. The feeling of confidence is well grounded. It will take a good while to turn back the hands of industry on the clock of national prosperity. No, we doubt if Rockefeller made the prediction attributed to him, but if he did, he had a motive. Time will tell.

By error, in last week's issue of the Cultivator, the credit was not given to the California Promotion Committee for courtesy of the use of the cut "The Golden Orange Harvest in Riverside." The committee is doing a great amount of work in showing the merits of California, spending much money and attracting settlers from all parts of the East. Not the least of its efforts is the publication of "For California," always filled with information for new-comers.

By an exeuctive order, the President created one of the largest forest reserve in the world this week. Four hundred and sixty-five thousand, nine hundred acres of virgin timber land in Southwest Utah, located in Washington and Iron counties, are to be cared for by the United States. The government expects to show what can be done with scientific forestry in the saving of big forests.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

It is claimed that the Toluca valley has been sending from $1000 to $1500 worth of fruit and melons to Los Angeles every day since June.

The Experiment Station has three experts now at Vacaville engaged in pear blight work who will help the pear growers in combating this disease.

The Santa Ana valley Walnut Growers' Association are arranging to receive walnuts about October 1st. The crop in that vicicinty is reported to be ten per cent less than last year.

The Arlington Heights Fruit Company at Riverside, is adding to the groves by planting one hundred and seventy-five acres of lemons and two hundred and fifty acres of oranges.

The Diddle ranch in Mendocino county, consisting of three hundred and ninety acres, was sold last week to an Italian colony who will sub-divide it into twenty acre tracts and plant to vineyards.

The seedless grape crop in Sutter county has been very good this year and the harvest is nearly completed. About four hundred boxes have been shipped daily to Portland and San Francisco, but most of the grapes have been used for drying.

A dispatch from Santa Rosa states that all the wineries in that county are running full blast and the prices for wine grapes have advanced to about $18 per ton, though some varieties are bringing as high as $20 and in one case a sale is reported at $22 per ton.

At the annual meeting of the American Pomological Society held at Kansas City last Friday it was resolved to urge all congressmen to use their influence to secure the passing of legislation looking to the reduction for icing and refrigeration charges for the shipping of fruit.

The Redlands-Highland Fruit Exchange is a new organization of orange growers formed last week to market the crop of its members through the California Fruit Growers Exchange. The new association will have control of about one thousand cars. The main office will be at Redlands.

The California winery at Sacramento is crushing about three hundred tons of grapes a day, making thirty thousand gallons of wine. The company is paying from $12 to $15 for grapes, according to variety, and expect to produce not less than 1,500,000 gallons of wine by the end of the season.

The Fernando Press states that the owner of one of the largest olive plants in Southern California has offered the olive growers in that section from $30 to $35 per ton for oil olives on the trees, and it is thought that pickling olives will run from $60 per ton up. We hope to see these prices prevail, but they sound fabulous to us.

The C. C. U. has a crew of men at work fitting up packing houses in the Lindsay orange district, to be ready for shipments to commence about the 1st of November. The Union this year will run three houses—the Union house, the Lindsay Ranch Co. Association, and the new house built by Capt. Hutchinson, at that place.

The annual meeting of the Tulare County Citrus Fruit Exchange was held last week. The report showed that the membership had more than doubled since last season. The average f.o.b. price received the past year was as follows: Navels, $1.62; seedlings, $.92; lemons, $1.47; Valencias, $2.38. The Exchange shipped last season nearly 131,000 boxes and received for them $205,369.57.

The news is given out that Prof. E. H. Twight of the State University, has succeeded in finding the cause of the mysterious "red leaf" vine disease. The plague is due to the ravages of a tiny, eight-legged mite of the spider family. Professor Twight says he will check the spread of the scourge by killing the larval forms by spraying matured mites, and if any insects remain he will use sulphur later in the growing season.

It has been claimed by interested parties that the orange crop the coming year will be much heavier than the past season and this statement has been generally accepted by growers all through the southern part of the State. This statement seems to have been premature as it is now claimed by prominent fruit men at Redlands and Riverside that many of the older groves will have only a scant showing of fruit, and they claim that the output will be even less than for the past season.

In an interview with Alden Anderson, manager of the California Fruit Distributors, at Sacramento, last week, he stated that up to September 20th there had been shipped from this State a total of 5587 cars of fresh fruit. There are yet to go from 2300 to 3000 cars, the amount depending upon weather conditions. Mr. Anderson made the further statement that the fruit industry of the State as a whole will be better this year than ever before and that the shipments will bring to the State at least $4,000,000.

The annual meeting of the West Ontario Citrus Association was held last week. The annual report showed the season's shipments to have been one hundred and eighty-two cars, as compared with one hundred and fifty-six cars of the previous year. Cash paid to growers for oranges was $55,212.52 this season, as against $46,270.81 last. The average payment to members for all grades and pools of navels was $1.08 per hundred pounds, or $.74.9 per seventy pound box. For all grades of Valencias the average payment to members was $2.36 per box.

The harvesting of the apple crop in Pajaro valley is now on in earnest. Solid trains of this fruit are being sent out daily. Several of the packing houses are working night shifts to meet orders pouring in. Never before in the history of the valley was the crop so large, free from blemish and of such excellent quality and prospects are that prices will be unusually high during the whole season. The fruit now being shipped out is nearly all of Bellefleur variety. The heavy movement of Newtown pippins will commence about the 1st of October.

At the annual meeting of the Southern California Walnut Growers' Association, held at Los Angeles, Saturday, prices were fixed as follows: Soft shell walnuts, 13c per pound; standards, 12½c per pound; second grades at 4c below first grade. These prices are one cent higher than last year, owing to the shortage of nearly seventy-five cars, and the fact that the demand is increasing at a greater rate than the production. Orders are already in from eastern dealers covering nearly all the output from Southern California for this season. This association represents about 25,000 acres of walnut groves, the output last year being 506 cars of 20,000 pounds each.

AGRICULTURE.

The hop harvest in the Pajaro valley begins this week and, with few exceptions, the yield will be comparatively light.

Geo. C. Powers, manager of the Rancho Del Norte, Ventura county, estimates the bean crop at fifty per cent heavier than last year.

More alfalfa will be sown in the Imperial valley this fall than ever before. There will also be quite an acreage planted to vineyards and small orchards if the nursery stock can be secured.

H. F. Blanchard, from the Agricultural Department at Washington, arrived at Berkeley last week to assist Prof. T. W. Shaw in his work of conducting experiments designed to increase the gluten in California wheat.

H. H. Evans finished harvesting his big wheat crop in the Perris valley last week. His harvester had been at work seventy-two days and had cut over thirteen hundred acres of grain. The crop proved very good on the whole tract, parts of it making an average of seven sacks per acre. The quality of the grain was very good.

Here is a corn stalk story from Shasta county. John Smith, a farmer at Montgomery Creek, has four acres planted to corn of the ordinary kind that has grown to startling proportions. All over the field the stalks range from fifteen to sixteen feet tall and the lowest ears are too high to gather without the aid of a step ladder.

Articles of incorporation for the California Hop Growers' Association were filed at Sacramento last week. The new organization includes many of the prominent hop producers of the State and its purpose is the selling of hops owned by members who are producers. Agents of the association will be sent into eastern markets so that they will be able to place the crop of each member to the best advantage. The cost of marketing through the new organization will be simply the pro rata cost of selling.

LIVE STOCK.

Glanders are reported to have broken out among horses in the Lemon valley near Pomona.

A new dairy company has been incorporated with a capital stock of $75,000 with headquarters at La Mirada, Los Angeles county.

S. W. Culbertson recently shipped sixty head of dairy cows from Willows to his farm at Selma, and will go into the dairy business quite extensively.

The Chino Champion reports that poultry raisers about that town complain of losses to their flocks from chicken-pox, one party losing two hundred birds.

The new creamery building at Jacinto, Glenn county, is to be completed and ready for business by the 15th of October. N. A. Chisholm, well known in Southern California as a Jersey breeder, is the secretary of the new company.

The dairymen of the central part of the Imperial valley met at the new town of El Centro last week to discuss the feasibility of forming a stock company to start a creamery. It is claimed that backing can be had for the enterprise.

A correspondent in the Anaheim Gazette from Buena Park states that the dairy men in that section are dissatisfied with the price received for milk at the creameries and will, after October 1st, ship their milk to Los Angeles, to be sold at retail.

A new sheep shearing machine is being operated on a ranch near Santa Rosa and it is claimed that the machine and one man can shear two hundred sheep per day. The machine is built upon the same principles as a horse clipper, and the motive power is supplied by a two horse gasoline engine.

We learn that after October 1st the Pacific Creamery, located at Buena Park, will not take skimmed milk, nothing but cream is wanted. This new order is claimed to be brought about by the fact that the creamery has more condensed milk on hand than it has market for and until the surplus is disposed of only the cream will be handled.

Nearly all of the fall clip of wool is now at the warehouses at Red Bluff and Corning, and the growers are anxious for the market to open. The wool men are anticipating from eighteen to twenty cents a pound, while the buyers talk of twelve cents. Tehama county has over 600,000 head of sheep, making it one of the largest wool producing counties of the State.

A test trial is now being held at San Francisco to determine the constitutionality of the law passed at the last session of the legislature requiring all venders of butter to mark plainly on every package sold the weight contained in such package. At this trial, Robert Dietrich was fined $20 with the alternative of spending twenty days in jail for violating its conditions. He has applied to the Supreme Court for a writ of habeas corpus.

MISCELLANEOUS.

Hanford and Santa Rosa are each making an effort to secure the coming State Fruit Gowers' meeting.

The open air tuberculosis ward at Mendocino State hospital has proved such a success that the capacity has been greatly increased.

The King Fruit Co., of Pomona, is a new citrus marketing organization recently incorporated and has let the contract for the erection of a packing house near Ontario.

A dispatch states that the Internal Revenue Department has placed men in all the wineries and distilleries in the southern part of the State to supervise the fortification of sweet wine in accordance with the new law.

C. H. SESSIONS, ASSOCIATE EDITOR

DAIRY SIDE PROFITS.

A writer in the Ohio Farmer, in speaking of the side profits from the dairy, says:

It used to be thought that all there was to be gained from a dairy farm was the milk or butter produced. No effort was made to get anything out of it aside from the value of those products sold, unless it might be when now and then a "deacon skin" was turned off for a song or when a cow had become old and worn out as a member of the dairy farm household she was fatted and disposed of for beef or salted down for home consumption. The man who depends on that narrow line of revenue in these days has a pretty strenuous life to live. In fact, few now attempt to do it. There are numerous side issues with the dairy farmer. One of these is the fattening of calves. It has become quite profitable to do this. From every cow at least one calf may be sold at a price varying with the season of the year and the locality in which the farm is located, but averaging probably six dollars each. Then, there is the line of raising calves for disposal later in the season or as additions to the home dairy. Here considerable profit may be realized. Cream, the old-fashioned "Dutch cheese" and buttermilk have also a large place in the latterday income of the dairyman. And they all count up nicely when it comes to footing up for the year.

But there is still another branch of dairy farming which does not seem to be made as much of as it will be, in my opinion, in the near future. I refer to the matter of growing nice calves, of either sex, for sale to other dairymen. Here is a field which is not likely to be overcrowded for many years, if, indeed, it ever is. An acquaintance has for some years kept Holstein cattle. His farm being rented to a tenant, he has only had the general oversight of the stock himself and only slow progress has been made in this direction. Now, however, his tenant has awakened to the desirability of having a few nice calves or young cattle to sell each year. He sees that the sale of a single individual may, sometimes bring in almost, if not fully, as much clear money as he could get from a single cow by working the whole year round. Another gentleman informed me only recently that he often sold a single young cow or calf for fifty and sometimes seventy-five dollars. "I am going to do more on this plan," he said. "I think farmers ought to specialize more than they do. There is almost always someone who wants a nice, pure bred calf at some price. If we can take in as much for the calf as we do for the whole year's work from the mother, it seems to me it is worth looking after."

To do this successfully, a man should do some advertising. He may do this by using the pages of some good, reliable dairy and farm paper, or by attending the State and local fairs, or both. No one can sell what people do not know that he has. He must let it be known that he has good stock at fair and reasonable prices. For this purpose, nothing is better than a good farm paper.

In order to establish one's self well in this direction the dairyman must be honest. This is not a reflection upon the great body of dairymen. I believe that they, as a class, are upright men. My thought is, that it will not do to sell an animal which is known to be inferior at a high price. One such sale may be the means of a man's undoing. It ought to be, too. None of us likes to be deceived and tricked into paying a big price for a thing that was never and never will be worth the money. It takes years of hard work to build up a dairy, and if a man has what he believes to be a good sire or a likely mother and breeds right along from them, think of the time and the hope and the money that is lost and worse than lost if it turns out that his stock is worse than he had to begin with. But if a man is fair and honorable in his dealings; if he had a good line of stock and uses right methods of placing bis stock before the public, there is little room for doubt that valuable additions may be made to the dairyman's bank account.

THE HOUSEHOLD CARE OF MILK.

When milk has been found to contain impurities, or sours more quickly than it ought to, the fault is laid at the door of the milkman, the dealer, the milk station, the farmer or the cow; but in many instances it does not occur to the person who finds fault to lay it just where it belongs, but where it is seldom brought home, and that is to the housekeeper.

While the fact is a lamentable one, it is nevertheless a fact that 20 per cent of the housekeepers of this country know little or nothing of the way milk should be cared for. Sweet milk is good milk; sour milk is bad milk. So much the average housewife does know; but as to what makes sweet milk good, or sour milk bad, why milk sours and how to keep it from that condition—she knows mighty little.

When there is trouble with the milk supply, the consumer finds fault with the milkman; he in his turn blames the trouble to the farmer; the city and suburban daily press (whose ignorance on the whole subect is equalled only by its wild statements as to prevailing conditions) howls at the milk stations; and the superintendent of the station swears by all his gods that the milk was in perfect condition when it left him, and that any impurity or adulteration must have got into it after it reached the city; and so it goes. It has apparently never occurred to the minds of either the dealer, the newspaper editor, the creameryman or the farmer that no matter if the milk has been produced under the most perfect sanitary conditions, kept in the same state in the milk station, iced in transit, properly handled by the milk com-

Sharples TUBULAR CREAM SEPARATORS
Demand a Look Inside

DAIRY TUBULAR BOWL—All Apart
"Bucket bowl" separator makers falsely claim to make separators with light, simple, easy-to-wash bowls. We are the only makers who dare show a picture of our bowl—all others refuse. There are secret difficulties about other bowls the makers want to hide. Pictures would betray them. Other makers fear pictures. Our handsome Catalog Z-200 tells these secrets. Write for it today.

pany in the city and delivered to the consumer in the best possible condition, it will not keep sweet and wholesome if it is not properly cared for in the household.

Where does the milkman generally leave the milk bottle or pitcher or pail, or whatever receptacle the family puts out for him to fill? Generally where it stands for anywhere from one to three hours, with very often the sun shining full on it. Now that same milk has been handled carefully from the moment it left the udder of the cow to the time it was left on the doorstep to prevent two things—the introduction of any foreign matter, and a rise in temperature, both of which aid the rapid development of bacteria which sour the milk. In the case of bottled milk, the rising temperature alone is to be feared, as the bottle is hermetically sealed; but in the case of open pails, pitchers, etc., there is the added danger of dust and dirt, and even, if there should be disease in the neighborhood, the probability of the germs being conveyed to the milk. In such cases, is it fair to blame anybody but the careless housekeeper if the milk should quickly sour?

Too many housekeepers put the milk for safe keeping in the refrigerator with cold boiled onions, cabbage, turnips, cucumbers, melons, strawberries, etc., in close proximity to it. Very often it is not covered. When it is taken out for use, it has a queer taste, or is "just on the turn." Milk absorbs odors as a sponge does water.

Again, the housewife will sometimes find that the milk has a "decayed" taste, if we may use the expression—that is, a taste and even an odor of putrefaction. It is not sour, neither does it taste or smell like sour milk it is rather bad, and sometimes bitter. This will be the case when it has been kept in a dark closet or refrigerator for some time. There is a class of bacteria, called putrefactive bacteria, which thrive in darkness; and they give the milk the odor and taste above described. This applies to milk that has been pasteurized.

Another fruitful source of quick souring is the putting of milk into or keeping it in vessels that are not thoroughly cleansed. Any receptacle for milk should be perfectly smooth on the inside, with no ridges, flutings or crevices; it should be absolutely sweet and clean before the milk is put in it, and should be kept covered always. Never leave milk exposed to the air when not in use. After a bottle or pitcher or pail has been emptied of milk, rinse it out with cold water first; then with hot water and soap powder or ammonia, then with clean hot water; and lastly with clean cold water. If it is possible to keep these receptacles covered when not in use, do so; it keeps dust and dirt out of them. Never wipe the milk receptacle.

Almost every housekeeper will put back into the milk bottle the milk left over from a meal, mixing that which has not been on the table with that which has. This should not be done. Put on the table only what you will need, and place the rest in the ice box, tightly covered. If any should be left on the table, put in a separate receptacle. The milk that has been in use has a higher temperature than that in the ice box, and has also particles of dust in it from the air, and it will cause the keeping quality of the other milk to deteriorate, if mixed with it.

If, for any reason, ice is not available, milk may be kept sweet by standing the receptacle (which should always be covered) in a deep vessel of cold water, having the surface of the water higher than the level of the milk. It is best to keep water running into the vessel, if possible. Another way is to wrap a cloth—flannel is the best kind—very wet with cold water around the bottle or pitcher in which the milk is contained, and stand it in a current of air. Keep the cloth wet, and your milk will keep almost as well as if on ice.

I wonder how many housewives can truthfully say that they return, sweet and clean, all the milk bottles the milkman leaves at their doors Do not a good many of us use one to keep vinegar in, another for cider, another for molasses, etc? Don't we generally feel much less concerned if we break a milk bottle than if we break a cup or a plate? Let's be honest about it—we do. Perhaps if we all knew that every milk bottle cost the company from five to six cents, and that every milk company of any size uses thousands of them every day, we would be more careful to return them. The money locked up in bottles amounts to thousands of dollars every year; and when the net profit on a quart of milk is but ½c, every bottle is an item to be considered. Be fair to your milkman—give him back all the bottles he lends you; and for health's sake, give them back clean.

Nowadays every effort is made, from the time the milk leaves the udder of the cow until it is left at the home of the consumer, to observe two rules, viz., keep the milk clean, and keep it cold. It is the housewife's duty to see that these rules are still observed in the household. If she does not, the milk will lose in wholesomeness and palatability and the fault will lie, not with the long-suffering milkman, but with herself.—Country Gentleman.

A MODEL DAIRY.

The editor of the Sacramento Union describes, in a recent issue, a visit to a model dairy farm—that of J. W. Rea, in the Santa Clara valley. He describes at length the cement floors, cemented corrals, automatic weighing device, separators, pasteurizers, automatic milk bottler, milkers clothed in white duck, and especially the economy with which all the work is done. "The whole operation from the milkman's bucket to the distributing jar or bottle takes but a few minutes, and is automatic in the sense that at no point does the milk come in contact with anything excepting the pipes and machines above described, all of which are thoroughly cleansed with boiling water before and after each operation. Within ten minutes from the time the milk leaves the cow's udder it is cleansed, Pasteurized, chilled, bottled and sealed—warranted to keep pure and sweet in ordinary weather from forty-eight to sixty hours, or more than double the period under the ordinary processes.

"It was interesting to observe that the whole operation for the product of 100 cows from the milkman's bucket to the sealed jar ready for delivery was done easily by two men, both spotless in suits of white duck. The amount of labor, therefore, required for preparing the milk for distribution is less than that called for under the old system—or no system—almost universally employed. Thus two men with the aid of a mechanical plant carry on a work at once elaborate and simple, prescribed by the modern or scientific plan of handling milk."

But as to the moral and principal point made in the article, we note:

"Without men skilled in dairy processes, Mr. Rea's enterprise and capital, the principles developed by science and the devices provided by inventive and manufacturing art, would be useless. If the system enforced in Mr. Rea's model dairy is to become universal in California, if we are to have everywhere a sufficient supply of clean,

pure, wholesome milk and milk products, we must have an agency for the training of men in dairy work. The men in white duck who do the work in Mr. Rea's dairy must be duplicated in every dairy in the country.

Now, with all due respect to President Wheeler, the academic atmosphere of Berkeley will not produce such men in sufficient numbers to do this work. The training at Berkeley may indeed produce chemists competent to devise plans and direct the work of others, but it will not produce the army of men necessary to do the work. The development of such an army calls for another training, another stimulus, another atmosphere. Industry as distinct from science cannot be taught practically in a scientific school and in an academic environment.

Here is where the necessity for a special school in support of agricultural industry demonstrates itself. Here is the justification for the provision made by the last legislature for an agricultural establishment separate and apart from the University at Berkeley, organized for the promotion of practical industry, dominated by the ambitions and aims of practical work as distinct from scientific study."

DAIRY SHOW AT CHICAGO.

The dairy interests expect to have a national dairy show at Chicago during the month of February. This show will be to the dairy interests what the International Fat Stock Show is to the beef interests. Several thousand delegates are expected to be present; dairy associations, butter makers, cheese makers, creamery owners and operators will be in attendance. The best dairy cows in the country will be on exhibition and will be tested for milk and butter fat. A model creamery will be fitted out and operated and lectures on modern methods of butter and cheese making will be given. The exhibition will be held in the basement of the Coliseum.

Queries and Suggestions

LEAKING PIPE.

Regarding loss of water through porous pipe asked about in the last Cultivator, Edwin Squire, a civil engineer of Claremont, writes as follows.

Editor Cultivator: If S. F. and P. of Redlands, will run muddy water through their leaking cement pipe, I think it will, in a measure, stop the leakage. I have known this treatment to prove effective in very bad cases. If possible the clay should be thrown in just at or above a sand-box, in order to prevent sand or gravel being carried into the pipe where it might lodge and cause trouble. The line should be run full if possible so the particles of clay and very fine sand may reach every pore.—Edwin Squire, Claremont.

MORNING GLORY—FINGER STAINS

Editor Cultivator: Enclosed you will find two vines which I would like to have you tell me through the columns of the Cultivator what they are. The flower of the smaller slip is something like a morning glory, of an orange yellow color, but I have never seen the blossom of the other plant, however, I suspect that they are both morning glories. Is there any danger of their spreading through an orchard where a few plants have appeared, and if so the best method to get rid of them?

Some time ago I saw in the columns of the Cultivator a recipe to remove walnut stains from the hands, but have been unable to find it again. Would you be kind enough to publish it again?—Gas. S.

Your plants are doubtless both of the morning glory family, the yellow flowering one is probably an introduced plant, Dichondra repens by name; the other may be any one of two or three species of Convolulus (morning glory). No one can identify plants without at least having flowers.

There is danger of their spreading; at least it is well to watch them to determine that point. If of the "Hedge Bindweed" or Asiatic morning glory, it's a terror. Digging or cultivation is unable to cope with it unless exceedingly persistent. Methods of control given in the Cultivator in the past: Cover ground heavily with salt, so thick a coating that leaves cannot push through. This "kills" the ground for two or three years. 2. Scoop out the ground above roots, fill basin with brine. Repeat in couple of weeks. 3. Cover ground with tarred paper after rolling and smoothing ground as evenly as possible. Hold down with dirt or stones all edges so as to exclude air and light. This will in time starve out the plant.

The material best adapted to remove walnut stains from fingers is the regular bleaching compound used in bleaching English walnuts. It is harmless to the hands and is made as follows:

Sal soda	16 pounds.
Chloride lime	20 pounds.
Sulphuric acid	1-4 pound.
Water, to make	50 gallons.

To prepare the bleaching solution, proceed as follows: Dissolve the sal soda in hot water and pour into a hardwood barrel having a wooden faucet about five inches above the bottom. Place the proper amount of chloride of lime in a tight-bottomed box and reduce it to a paste by using a hoe and a small quantity of water. Then put the paste into the barrel with the dissolved sal soda, and fill to 45 gallons with clear water. Mix it thoroughly and allow it to stand 48 hours before using, so that all the sediment may be on the bottoms and the liquid clear. When ready for use pour five gallons of water into an earthen jar and add the sulphuric acid very slowly—a few spoonfuls at a time—until all is added. Walnuts are dipped in this solution for about a half minute.

OPPORTUNITY FOR NEWCOMERS.

Editor Cultivator: We have been reading the Cultivator for several months and enjoy it very much. I have read considerable of California and have decided to make a trip there. Will you please advise me if there is any work to be had in the fresh air. What section is most healthy for lungs? Is there many opportunities for one with a small capital. Is the poultry business a success? How much land would one have to have to make it pay? What does land cost with matured walnut trees on it? I will thank you very much if you will answer through the columns of your paper. Also I would like to ask, is there good clay in California for the manufacture of bricks, and what kind of brick is made there. —W. W. Nuzum, Rochester, Pa.

That class of question is the hardest to answer of any which comes to this office. There is work to be had. Whether one not physically strong can get work, it is hard to say. Most of the dryer valleys are favorable to persons with weak lungs. There are opportunities for small capital, many having come here and done well. The poultry business is a success; it has made money for many. It is likewise a failure and has lost money for some. It depends, like every other business under the sun, on the management. Have you been a success with poultry in Pennsylvania and can you open your eyes to the fact that California conditions demand certain changes from the successful methods of Pennsylvania? If so, you can succeed here. If you have no experience, you should not be too hopeful of complete success here till you have felt your way and "learned the business." If you have grit and determination you willl learn and succeed. The amount of land needed may be a town lot or several acres. There are little ranches of two or three or ten acres near Los Angeles where the owners started with very small capital, and today have a comfortable home paid for. Bearing walnut groves, of thrifty and well cared for trees, command big money, say from $500 to $1000 per acre.

Clay is found here of finest quality and is used for all kinds of products, from fine pottery to sewer pipe, to pressed brick, fire brick and the coarsest and cheapest of brick.

STRAWBERRIES.

Editor Cultivator: Will strawberry plants which were set out one year ago and bore a full crop this season bear a full crop next season? or will I have to set out new plants? They are in matted rows. How will it do to dig up old original plants and let runners be? or shall I cut tops all off and let them come out anew?—Subscriber, Fallbrook.

You should have pinched off all runners and retained the original plant. As they are now matted together you will not get as large, fine berries, but as they are only a year old it will, perhaps, be wise to get out at least next spring's crop before replanting. Then plow up, manure heavily, replant with thrifty plants. Keep in rows to original "hill" and they will be productive of large berries for three years, if given good care and of good variety.

THOMPSON'S SEEDLESS GRAPE CUTTINGS.

E. E. Gerry, of Santa Paula, writes that he is able to supply recent inquirer with cuttings of Thompson's Seedless grape.

BORERS ON PEACH TREES.

Mr. Edwards of San Martin, wants to know how to rid his peach and prune trees of borers.

"The best remedy is prevention." Or, in other words, keep the trees from becoming sunburnt, which will in a measure keep the borers from entering the wood. They may be removed by chiseling out or using wire to remove them, but in such a case, so far as possible remove all dead or diseased wood. Another and more simple remedy is to smear around the trunk of the trees at and below the surface of ground with a mixture of four gallons of crude oil, being careful to select a heavy grade of oil, mixed with thirty pounds of lime. This is the remedy, we believe, which is now used most generally in the prune orchards of the Santa Clara valley.

COVER CROP.

Editor Cultivator: Will you please tell me what you think of planting peas for a cover crop for potatoes? At what time should I plant so as to turn in about the first of February? Would you recommend sowing rape with the peas? Where can I obtain the seed?—D. R. M., Compton.

The use of peas or any leguminous plant for the cover crop for potatoes would doubtless put the ground in much better shape, both mechanically and furnishing it with humus and increasing available fertility. You should plant at once if water can be had for fitting the ground. If not, at the very earliest possible moment. If the rains should hold off until late, you may be unable to secure the proper growth before it would be necessary to turn under and cover. They should be turned under while still green and succulent and some time before the planting of the potatoes to allow at least partial decay of the stems. We have not heard of sowing rape with the legume and do not think it would add anything to the value of the cover crop, providing a good stand of the peas is secured.

MEAT MEAL FOR GROWING PIGS.

J. R. Zuck, of Gilroy, asks if it is advisable to add any meat meal, bone meal, or blood meal, to the usual bran and middlings diet for young growing pigs.

The use of blood or meat meal has been most highly recommended for young, growing stock, especially pigs and calves. A pint of the meat meal or about the same of blood meal may be added to a twenty-four hour feed for ten pigs.

ALMONDS.

Editor Cultivator: Is hill ground well suited to almond culture. Also whether they need a rich or sandy soil and irrigation?—D. H. S., Santa Barbara.

Regarding location for almonds, Wickson's Fruits says:

"Almonds are now doing best on the higher lands in coast valleys, free from fogs and protected from direct winds, but subject to tempered breezes; also at various points in the interior valleys and foothills. The general proposition that lowlands in small valleys shuold be avoided, and bench or hillside situations preferred, seems to be a safe one. Lands directly upon the coast have not proved satisfactory. The almond prefers a loose, light, warm soil, and heavy, poorly drained soils should be avoided. Though they need moisture enough to make good, thrifty growth, they will produce good crops on soils that are too light or dry to grow satisfactory peaches, apricots, nectarines, cherries, or similar pulpy fruit."

From the above we take it that the almond would prefer the rich, naturally sub-irrigated soils, but in case the condition is not ideal, we take it that, without question, irrigation would be an advantage.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

ROUP CURES.

"I wish you would describe roup," writes a beginner, "so that I may know the disease when I see it."

The symptoms at the commencement of roup are those of simple catarrh and at first these two diseases cannot be distinguished from each other. Roup is very much like "grippe" or influenza in the human family and it is customary to call almost any ailment in the poultry yard "roup." Dr. Salmon in his learned book on the diseases of poultry under the head of roup, divides it into simple catarrh, roupy catarrh, bronchitis, pneumonia, congestion of the lungs and diphtheria. I think these should be considered as six different diseases, commencing with many of the same symptoms, but varying as they progress.

Roup commences like catarrh. The first symptoms noticed are a slight discharge from the nostrils, eyes wet and watery from mucus, and often some bubbling at the inner corners, with coughing and sneezing. So far the two diseases are similar; in a few days the catarrh will not have developed more serious symptoms, but with roup the discharge from the nostrils thickens, has a very offensive odor and obstructs the breathing. There is no odor in catarrh, but it is always present in roup. Sometimes the head swells, the eyes, one or both, close up, the bird becomes feverish, listless and without appetite. The birds wipe their eyes upon their shoulders, sleep with their heads under their wings and the discharge sticks to and dries on their feathers. This dried mucus will spread the disease, so chickens that have been using their wings as a pocket handkerchief should be separated from the rest of the flock, the mucus gently washed off, using a good disinfectant in the water. A few drops, or better still, a tablet of bi-chloride of mercury will kill the germs.

Simple catarrh, like a simple cold in the head in the human family, is not dangerous and can be easily cured if taken in the early stages. Roupy catarrh is more difficult of cure, is very infectious and often fatal. Diphtheritic roup is the worst of all. It is as deadly as diphtheria among children, and it requires different remedies to the catarrh or roupy catarrh. We will take the remedies for the first two.

In the treatment of roup the most satisfactory way to get the medicines where they will do the most good is though the use of an atomizer. I have, however, found a little sewing machine oil can a good, cheap and effective means of administring many remedies.

* * *

Remedies.—Influenza in fowls, as in the human family, can be treated in a great variety of ways and it is well to remember that the same remedies that are used in the human family can be used very effectively with fowls; for instance a pill of quinine and one of assafoetida, with half a teaspoonful of cayenne pepper, will frequently cure a cold in one night. Aconite also is a great help. I give one drop in a teaspoonful of milk, and that frequently cures in a night.

* * *

My Remedy, No. 1.—One tablespoonful of castor oil, half a tablespoonful turpentine, half a tablespoonful coal oil, six drops carbolic acid and half a teaspoonful of spirits of camphor. This I keep in a sewing machine can and squirt a drop up each nostril and into the cleft in the roof of the mouth, and for swelled head rub the whole head with it. This is an excellent roup cure, and cheap.

* * *

My remedy, No. 2.—A bit of blue stone (sulphate of copper) in the drinking water. A piece the size of a navy bean to a quart of water. This is very cleansing, is a germ killer, dries up the cold in the head, and is a great preventive of roup. If any chick takes cold, that whole pen has blue stone in the drinking water for a week to prevent the infection spreading.

* * *

Remedy No. 3.—A lady friend of mine, who has been fifty years in California and has been very successful with fowls, told me that after trying many of the so-called "roup cures," she, for the last thirty years, has found common kerosene oil the best cure. She pours one cupful of the oil into about three quarts of water in a pail; the oil floats on top. She then dips the whole head of the bird into this, holds it there whilst she counts one, two, three, slowly. The bird then coughs and sneezes and she wipes the mucus off with a rag, which she carefully burns. This is repeated twice a day, and she says it is a "sure cure."

* * *

Remedy No. 4.—A. F. Hunter, one of the oldest poultrymen in the East, gives the following remedy, which I have tried and found good: Take of lard two tablespoonfuls; of vinegar, mustard, cayenne pepper each one tablespoonful; mix thoroughly, and flour enough to make a stiff dough. Give a slug, about the size of the first joint of the little finger. One dose frequently cures, if not repeat in twelve or twenty-four hours.

* * *

Remedy No. 5.—Dr. N. W. Sanborn, in his "Reliable Poultry Remedies," says: "When you find a bird sneezing, or you notice a slight discharge from the nostrils, spray all mucus surfaces with the following: Extract of witch-hazel, four tablespoonfuls; liquid carbolic acid, four drops; water two tablespoonfuls. Do this twice a day, squeezing the bulb of the atomizer five times for each nostril and twice for the mouth. If there is any watery or foamy eyes, give one squeeze for each.

* * *

Remedy No. 6.—A medical friend gave me the following recipe, which he says acts like magic in curing a cold in the head in the human family and he thinks would be a sure cure for catarrh in fowls: One part of pulverized gum camphor and seven parts of

PETALUMA INCUBATORS
—AND—
BROODERS

The acknowledged standards of perfection. All poultrymen who have used these machines have supreme confidence in their ability to hatch and brood. Hence their ever increasing popularity. Winners of the GOLD MEDAL at the St. Louis World's Fair for greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1604.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A FILCHER, Commissioner.

Sumptuously illustrated catalogue free; write for one at once. Send for our poultry supply catalogue No. 47, describing our line of supplies. Everything for the Poultrymen.

powdered liquorice root. Snuff up the nostril for the human beings and for poultry blow up the nostrils and into the cleft of the mouth and down the throat. This should be made fresh as the camphor evaporates and loses its strength very soon.

* * *

Remedy No. 7.—For diphtheritic roup a very clever doctor, who was also a chicken raiser, many years ago gave me this: Equal parts of powdered alum, magnesia and sulphur blown into the throat and nostrils through a quill.

* * *

Remedy No. 8.—The best remedy now known for diphtheritic roup, or you might call it diphtheria, is undoubtedly peroxide of hydrogen. This is death to germs. It is a liquid, coming in strong bottles, tightly corked, and requires to be diluted with from three to six parts of water, according to the severity of the case. There is a good preparation of this, known as "hydrozone," that is often to be found at the drug stores. The solutions when applied to diseased surfaces at once begin to foam, and should be repeated until there is no more bubbling. A little of the solution forced into the nostrils by the use of a dropping tube or the atomizer is driven higher up into the nostrils by the force of the foaming, reaching parts otherwise out of touch. The worse the case, the stronger should be the solution and the longer it must be used.

* * *

These remedies, or "roup cures", are all good, most of them have been tested and tried for years, and may be used without hesitation for they are sure to give good results, still "prevention is better than cure." The diet in roup should be simple. Green food should be within reach at all times and all mashes should have at least one-third of their bulk of clover or alfalfa. Drinking water should be changed twice a day.

* * *

EDITOR'S QUESTION BOX.

Mrs. A. Basley has taken a month's vacation, to visit the Portland exhibition and other points north, therefore after today she will not be able to answer questions in her box until her return.

* * *

Geese.—(Mrs. E. A. P.): I am interested in geese and have very good success, but wish to know if they can be made to lay so the goslings will be ready for market in January, February and March, as they bring a higher price then than later. Can you give me the name of some publication that treats on the subject of geese, both for market and for feathers?

Answer.—The Reliable Poultry Publishing Co. have a book, price 50 cents, which is called "Ducks and Geese." This will, I think, give you all the information you require. You can get it at any good poultry supply house, or you can write to the Secretary of Agriculture at Washington and ask him to send you Farmers' Bulletin No. 64 on "Ducks and Geese." This will be sent to you free in about two weeks after you apply.

* * *

Hoppers.—(Mrs. J. W. B.): I have been reading in the Cultivator the articles on dry feeding for poultry, and would like to ask if you can describe how to make the hopper to feed the dry mixture in. I see the plan of one in the paper, but I guess my head is rather thick, so I don't just understand how it is made and I should like to try that plan of feeding, as I am not able to attend to making mashes, and like the plan of dry feeding. I would like to ask what the dry meat scraps are and where they can be purchased. What do they cost? I have always used the meat, blood and bone meal, but, to feed dry, I should think the meat scraps would be best.

Answer.—I made the hopper or feed box myself out of a cracker box and gave a plan of it in the Cultivator. If you can not make one you can buy a galvanized iron hopper at any poultry supply store and if you want a larger feeder, copy it in wood. Or nail a ten pound lard can against the wall and put the feed in that, only half filling it.

The dry meat scraps are made of beef, which is cooked and all the grease squeezed out of it at the packing houses. It is then dried and ground. Beef scrap can be bought at the poultry supply houses and costs about three and a half dollars a hundred pounds. A hen eats about half an ounce a day. See my reply to Miss P. M. W.

* * *

Dry Feeding.—(P. M. W.): Will you kindly state, in the Cultivator, if I can begin the dry feeding with my old hens, or must it be begun with little chicks? How can I feed Calfalfa meal dry? I hardly think the hens or chicks could or would eat it dry. If I can start in dry feeding my young pullets and last year's hens, please give me a balanced ration for dry feeding.

Answer.—You can begin dry feeding at any time, remembering always that any sudden change will for a time affect the egg basket. The change may be made gradually, such as by giving the dry feed at first during the day and a light mash at the usual hours.

I will tell you how I feed, and the proportions—but I really would advise you to write to the director of the Experiment Station, Berkeley, Cal., for the Bulletin No. 164 on poultry feeding. There you will find a number of good recipes.

What I am now feeding in a home-made hopper, or a bucket nailed to the wall, is three parts bran, 2 parts alfalfa meal, one part corn meal. I put these into a bin, mix them together and then take a bucket and fill up the

hopper. At the same time I keep a hopper full of beef scraps always before the hens, besides grit, shell and charcoal, they have table scraps and all the skim milk I can spare them, and the remnants of vegetables and squashes or pumpkins.

They balance their own rations and lay marvelously. My hens are White Rocks, and until now it has required very careful feeding not to over-feed in some particular direction, as they are apt to lay on fat quickly; with White Leghorns you would not have this difficulty, as they are of a nervous, active temperament, always on the move; they can stand more carbonaceous diet than the American breeds.

The reason I advise you to write for the bulletin on feeding is that you may be able to substitute some grain that you can purchase very cheaply and by finding out through the bulletin the nutritive value of the grains you can make your own balanced ration and use the cheaper grain. The bulletin is furnished free of charge.

* * *

Tuberculosis.—(G. H.): I have some chickens, young and old, that have tuberculosis. Can you tell me what to do?

Send to State University, Berkeley, for Bulletin No. 161, Tuberculosis in Fowls. Meantime separate all well fowls, put them on fresh ground. Isolate the diseased ones—or better, kill and bury deeply. Then thoroughly disinfect and let in sunshine to old quarters.

CLEANING ROOSTS.

The proper way to clean a roost, says Epitomist, is to first carry everything out of doors, roost poles, nest boxes and loose boards. Give them a dose of oil and apply the match. If the wood takes fire it can be put out by throwing sand on it. Now rake out all fowl dirt, and give the inside a good coating of whitewash. Do this once a month. If we do not have time for all this, then get some liquid lice paint and go over the roost poles, nest boxes, etc., with a brush dipped in the paint. Put on a good coat. This should be done just before the fowls go to roost at night. Probably the fowls will not like the smell, but drive them all in and shut the house up tight for an hour or two. This will not only kill the red and gray mites, but all the body lice on the hens as well. In ten days (after the lice eggs previously laid are about all hatched out) repeat the operation, when we may reasonably know that our hens and roosts are freen from lice and will stay so for a month or two.

GAPES.

Gapes are caused by trematode worms in the windpipe and occur usually in young chickens. These worms are from 1-5 to ½ inch long, reddish color, and found attached to the windpipe. The number of worms may be increased until the fowl is completely choked. These worms are frequently removed by means of a wire or horse hair doubled so as to form a loop which is inserted into the windpipe and turned until the worms are all removed. A simple method is to dip a feather in turpentine or kerosene, thrust it into the windpipe and turn until the worms are removed.

Keep little turkeys free from lice. Do not over feed them. Keep coops clean and dry.

ADVERTISE YOUR YARDS.

Do you some day wish to derive enough profit from your poultry to make a very comfortable living? If so you need to get a move on yourself. Don't sit in the shade wating for business to grow. It may be something new to you, your only experience in the line of advertising being derived from inserting an ad in the want or for sale columns of your local newspaper.

As a rule large space pays better than small. But yet if you will toot your tooter every week of the year and year in and year out you will soon have a nice business, notwithstanding that you probably used only one inch of space each issue. But you kept everlastingly at it and there is where you made progress for the "stick-to-a-tiveness" is the main thing in poultry advertising.

If you contemplate taking space and are a beginner, drop the editor a line, place confidence in him and describe to him the full situation and he will take pleasure in giving you personal and reliable advice. Do not think the rates are too high; true enough they may be for the man who expects to advertise one month out of the year, for the regular advertiser has won the confidence of the readers while the occasional advertiser has it to win. Again let me advise you to advertise in fall, winter, spring and summer.

WHY FAILURE.

Compared with failures there are few successes, because—

1st. Lack of adaptability.

2d. Lack of working capital.

3d. Selecting the wrong breed for the purpose intended.

4th. Lack of business understanding.

5th. Neglect of details.

6th. Too many fowls to start with.

7th. Starting with poor stock, which never pays.

8th. Improper feeding.

9th. Lacking energy; too easily discouraged.

10th. Not being rightly fixed for keeping fowls.

11th. Over-crowding; lice, mites.

12th. Neglect to advertise, not one time but all the time. Because no breeder can have any success who does not advertise.

These are some causes of failure, and there are others.

Carbolic acid fumes are good for roup. Shut the fowls up in dry quarters and fumigate by putting a few drops of acid on a hot shovel or pan.

Look out for the mite. Spray the perches, nests and interior of the poultry house with kerosene and lime.

FEEDER FOR YOUNG CHICKENS.

Take woven wire, not chicken wire, about 26 or 30 inches high and 20 feet long, bring the ends together and tie with strong twine. You then have a round feeder complete. The young chickens go in between the wires, while the old ones will walk around seeking a place to creep through but never fly oved. Wire with stiff stays is best to make it of. After the chickens are grown the strings can be cut, wire rolled up nad laid away for another year. I have tried these feeders and know they are good.—Farmer's Guide.

A NEW POULTRY JOURNAL.

Volume one, number one, of the Jubilee Poultry Journal is sent us by the Jubilee Publishing Co., of Sunnyvale, Santa Clara county. It's a beautiful monthly magazine of 28 pages and cover. It is well edited, well printed and a credit to its publishers.

Besides its announcements, it has several articles on Trap Nests, Why Some Poultry Doesn't Pay, Feeding of Poultry, etc.

Strong, healthy fowls are not subject to roup or disease. They can endure the vicissitudes of the weather almost with impunity. They go out in the rain, and do not get roup. They may roost on fences, trees, woodpiles—anywhere; and rain may fall on them, cover them, yet they do not get roupy. In fact, they can stand all kinds of exposure, without the development of even a tendency to roup. Close bred, pampered birds can not do this. Human consumption comes from the pampered, close housed class. The person who is always in the open air in all sorts of weather never contracts consumption. Inbreeding is one of the causes, if not the main cause of lack of constitutional vigor in strains.

A Visit to the Large Packing Houses in the Eastern Cities

In Three Chapters.==Part II.

BY A. R. COULSON.

ARMOUR PACKING CO., KANSAS CITY.

The Armour Packing Company at Kansas City have about the largest and best equipped slaughter houses and packing plant in the entire world. Everything was built, not only for convenience, but also for cleanliness as well; in fact, it is kept much cleaner than a person would think it possible to be. And, as for machinery, one would be astonished to see the great variety of machinery of various kinds that they have at this institution.

Engines of 1000 horse power, huge furnaces, boilers many feet long, tanks several stories high, besides their own can-making factory, one of the largest in the world, as well as a box factory and other factories.

Another thing unusual for large institutions of this kind; the company here owns all land, not only that which is covered by the buildings they occupy, but also the streets as well: and they have a high stone wall around the whole business, reminding one of the Chinese wall.

It is virtually a city within a city. They have between 6000 and 7000 hands employed here, and therefore are the means of supporting many families, probably aggregating between 20,000 and 25,000 people, many of whom live at Armourdale and surrounding vicinity.

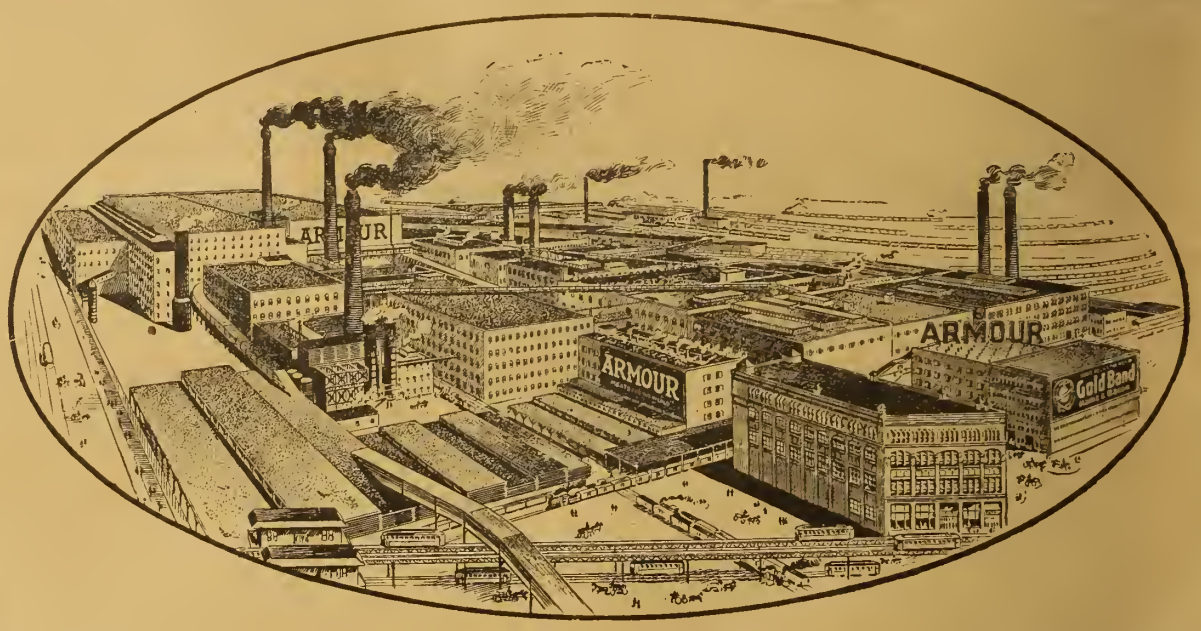
At every entrance and also scattered throughout the yards are numbers of special policemen and no suspicious persons are allowed to enter, unless they give a good account of their business, and then they are closely watched.

The writer went into the main four-story office building and gave his card to one of the attendants that came forward and requested to be taken to Mr. Futvoye, the manager of the animal food department. The writer then followed the attendant through rows and rows of general office men, heads of various departments, clerks, book-keepers, stenographers, telegraph operators, etc., altogether there are nearly 300 of them, keeping account and carrying on business with all parts of the world.

Mr. Futvoye took the writer all through the various departments, and also into the basement of the office building, showing the machinery and appliances used for washing the air and circulating it through the building. The air is sucked in from above the roof and it comes down through a passage-way in the basement where it passes through a room where the water pours down like rain and washes all the particles of dust and germs from the air. The water afterwards looks very muddy, showing how much dirt there is in the air. The clear pure air then rushes on and passes through a sort of electrical or drying machine, and from there it is fanned up into the different office rooms. The office windows are never opened, hence no dust; the pure air goes in one place and the impure air is sucked out at another.

We then walked from the great office building in the State of Kansas over into where the killing was going on in the State of Missouri. This building is hundreds of feet wide and many hundreds of feet long. The cattle killing is done in one part, and the hogs in another department, and the sheep in another.

A couple of carloads of young, fat long horned steers came in at that moment, and they were run in through long, narrow alleyways, just wide enough for two; and a trap door was let down between them, about every eight feet apart, leaving two steers in each department. They were made to jump around until one faced one way and one the other. Between these two long rows of cattle in boxes, was a space of about four feet wide, where the men who did the killing, walked along. Two men with sledge hammers, one at one end of the row and one at the other, did the killing—they would lift up their hammer above the head and give the steer one whack on the forehead and down it went. Then he would give the other one a whack, and then he touched a button,



Plant of the Armour Packing Company at Kansas City. It is a city within a city. Here they employ between 6000 and 7000 people and they kill from 6000 to 10,000 animals a day. The hearts and livers from these animals are cooked and baked and made into meat meal and this is shipped in carload lots to the Coulson Poultry and Stock Food Company who use it in making Coulson's Egg Food and COULSON'S SPECIAL CHICK FOOD.

Unloading hogs from stock cars and driving them into the slaughter house at Armour Packing Company's.

Skinning and dressing beef at Armour's. The hearts and livers are kept out by themselves and are cooked and baked and used in mixing Coulson's Special Chick Feed.

and the two animals would slide down through a trap door to another department, where men would hook them on to a big chain by the hind leg and off they would go.

The first thing that was done—they were cut in the breast and the blood was drawn off in buckets, and then emptied into big cooking tanks, where it cooked for a few minutes until it thickens, then it goes into a revolving heated cylinder, and in ten minutes it is made into dried blood. Then it is put up in 100 lb. sacks and every few days a carload is shipped to Coulson Poultry & Stock Food Co., at Petaluma, Cal., and is used by them in making Coulson's Balanced Rations for poultry and stock.

The next minute the animal slides along another ten feet and the hide is taken off; and in another minute, it is in the dressing department, and ten minutes later it is hanging up in halves in the refrigerator department. In this length of time it has probably been handled by no less than one hundred people, as each has one particular thing to do.

The hearts and livers and kidneys are put into one big pile by themselves. These are then put on to big steel pans about fifteen feet square and these pans are put into big ovens, where they are piled in layers, or drawer-like, and fit one on top of the other into furnaces about twenty-five feet high. They are first roasted to a crisp, and are then taken out and allowed to cool until the next day. Then they are put through another process of baking or drying, by means of a heated cylinder, or long boiler with a big screw running through the center, which keeps stirring them up, and in another hour they come out at the other end, converted into meal, (Baked Hearts and Liver Meal.)

This product is then put up in 100 pound bags and 400 sacks (or 40,000 pounds) are put in a refrigerator car and shipped to the Coulson Poultry & Stock Food Co., at Petaluma, Cal., who use it in making Coulson's Egg Food, and Coulson's Special Chick Feed.

As space is limited the writer cannot go into all the details of what is to be seen in one of these big packing houses, as it would fill a book; but will conclude by mentioning the fact that the Armour Co., at this plant, kill as high as 3500 cattle, 4000 hogs and several thousand sheep in a single day.

On a big black-board in the office building each day are marked the receipts at the stockyards, which reads about like this:

Cattle receipts	12,320.
Hog receipts	14,280.
Sheep receipts	8,000.
Poultry receipts	12 cars.

The Coulson Company not only take all the products of Hearts and Livers Meal from this plant but also from Omaha, Chicago and St. Louis plants as well, and in short while the Coulson Company has paid the Armour Co., more than $50,000 for Hearts and Liver Meal and Dried Blood.

It is safe to say that the Coulson Company's sales of Coulson's Egg Food and Coulson's Special Dry Chick Food has been nearly 400 full carloads during the last fifteen months for the Pacific Coast, and they are soon to establish a branch factory at Omaha to supply the Middle West States.

If you have any poultry at all, you should feed them Coulson's Foods: Coulson's Egg Food for the pullets and hens, and Coulson's Special Chick Food for little chicks. But be sure to insist upon getting Coulson's for there are many imitations which will be offered cheaper, but they do not contain the good ingredients like Coulson's.

So remember—INSIST UPON HAVING COULSON'S.

Ask your dealer for Coulson's.

Photograph of a pile of about 25,000 baked and dried Hearts and Livers. These are to go through one more process of baking, which will thoroughly dry them, so that the meal will keep, without spoiling. This Hearts and Liver Meal is very tender, sweet and nice; it is easily digested and is great stuff to make chicks grow. It is used for making Coulson's Special Chick Feed.

A story about substitution, which is really the same thing as stealing.

SUBSTITUTION.

A copper cent shined up looks like a $5.00 gold piece to a person who is ignorant of the difference in the value of the two coins. He might wish to purchase one and he may have heard or been told that the gold was best, and he may ask for the gold. But the dishonest merchant will say: "Here is something just as good and it is cheaper, and you can have it for $4.00 and the other one costs $5.00.

And the customer looks at the two coins; the copper cent shined up looks to him as good as the $5.00 gold piece, and he thinks he has struck a bargain. So he pays $4.00 for a copper cent, thus paying the merchant 400 times as much as it is worth, while if he had paid $1.00 more, and got the $5.00 gold piece, he would have the worth of his money.

The moral of this story is, if you start out to buy a certain article, don't let the merchant do you, by selling you a substitute which is chaper.

If you want to buy Coulson's Egg Food, or Coulson's Chick Foods, insist upon having Coulson's and give them to understand that you know your own mind, and that you don't intend to be cheated by accepting any Substitutes.

OUR COLORS.

Red! 'tis the hue of battle,
The pledge of victory;
In sunset light, in northern night,
It flashes brave and free.
"Then paint with red thy banner,"
Quoth Freedom to the Land,
"And when thy sons go forth to war,
This sign be in their hand!"

White! 'tis a sign of purity,
Of everlasting truth;
The snowy robe of childhood,
The stainless mail of youth.
Then paint with white the banner,
And, pure as northern snow,
May these, thy stately children,
In truth and honor go.

Blue! 'tis the tint of heaven,
The morning's gold-shot arch,
The burning deep of noontide,
The stars' unending march.
Then paint with blue thy banner,
And bid thy children raise
At daybreak, noon and eventide,
Their hymn of love and praise.

Valor and truth and righteousness
In three-fold strength today,
Raise high the flag triumphant,
The banner glad and gay.
"And keep thou well thy colors,"
Quoth Freedom to the Land,
"And 'gainst a world of evil
Thy sons and thou will stand."

—Laura E. Richards.

Sweet Waters.

It was four o'clock in the morning, and the birds were already singing in the trees. The summer sun would soon be visible and the conglomeration of ashes, water, charred wood and burnt clothing would be gazed upon still more plainly by John Melvin and his family—all that was left of that which a few hours before had been their home.

Some of the neighboring farmers still stood around in sympathy.

"Well, John, it ain't as bad as if you didn't have any insurance. You know Dan Howell lost every penny when his barn burned."

"Oh, I know," was the answer, "but I could only afford to carry five hundred dollars, and you can see what this loss is—double that."

"I know—it's mighty bad. You'd better bring Mrs. Melvin and the two youngsters on over with me and get some breakfast; my wife'll be too glad to do something."

But Mrs. Melvin herself answered this offer.

"Thank you, Dick. Tell your wife I know how good she is, but Esther and I must get things in some kind of shape here, if that is possible," she added hopelessly, as she viewed the desolation before her and tried to speak without sobbing.

"Well, goodbye to you; let us help you in any way we can," and he, with one or two others, started across the fields.

"Here, father, I know we can arrange things so we can live on the farm until we can do better," Ralph said, trying his best to speak cheerfully. He was eighteen, even if Dick Jennings did call him a youngster.

Esther, who was two years younger, was saying to her mother, "Mamma, that chest of bedding was saved and most of the furniture. Will papa see about building a new house right away?"

"Oh, dear, I suppose so—as soon as he can. We can't do much with $500. It we had not saved the barn, we would have been dependent on the neighbors for shelter."

John went up to his wife, and, placing his hand on her shoulder, said, brokenly: "I don't seem to know what to do first, Carrie; I wonder if we could eat any breakfast if we had it?"

"Yes, dear, we could. You and Ralph get the cook stove set up and I'll try to find some coffee. Esther, get poor old Brownie out there and milk her. Before long we will have something to eat and then we will set to work."

She turned away, so they would not see that she was crying again.

In the course of an hour breakfast was laid in the only clean, cool spot near enough for the purpose. This was down by the spring house, where Esther had carried the large bucket of fresh milk, and was straining it into pans to cool. The almost ice-cold water bubbled up and rendered the atmosphere of the place like that of an immense refrigerator.

"Thank heaven, mamma, the spring couldn't burn!" exclaimed the girl, as she sat down on the grass beside her mother.

"Yes, that spring is one of the comforts left to us, I have been thankful for it a thousand times."

"What a funny breakfast!" said Ralph, as he helped himself to boiled roasting ears and boiled potatoes, but no bread. "It's a good thing we've got butter!"

"If we can get the stove to draw, I'll get some biscuits made some time today," said his mother. "John, dear, is the coffee all right?"

"Oh, yes. If it were not for the nasty burnt smell in the air, we could shut our eyes and imagine we were at a picnic," said John, bravely.

"Say, sis, I've always wanted to go camping—haven't you?" said Ralph, an ear of corn in one hand and his spoon in the other. "Where's the sugar?"

"Boiled into taffy and then burnt up, I suppose," answered Mrs. Melvin, grimly. "I wish I knew how we were going to get any more," she added.

"If we only had something to sell," sighed the father. "It will be weeks and weeks before the wheat or corn will be ready for the market. Mother, you will have to do your best with the butter, and what few chickens we have."

"What will you do for a while, my poor dears?" he thought in deep anguish, as he realized all the discomforts with which they would be surrounded until the new home could be made ready. But aloud he said to Ralph. "Now, my boy, we'll throw everything that we can possibly spare out of the barn and get the beds ready for night. God be thanked that it is summer time instead of winter."

But the hot August sun soon beamed down upon the unfortunate ones as they worked with a will to reduce the chaos.

The farm was situated too far from Chicago for the city fire department to be of any service to the Melvins in their need. But the $500 insurance would be like a small fortune to the now homeless family.

A neighboring farmer notified the company of Mr. Melvin's loss, and on the following day a couple of strangers drove through the lane.

Giving his lines a twist around the whip stock, the elder man descended and handed a card to Melvin, on which he read: "Parker Blackleigh, Protective Insurange Company."

"Glad to see you, Mr. Blackleigh. You can see how I am fixed here." And John waved his hand toward the black, foul-smelling debris.

Then turning to the other gentleman, who still remained seated in the buggy, he said. "Won't you get out, too, sir? You'll enjoy your ride all the more for stretching your legs a little."

"Thank you," was the answer, as a handsome young man of twenty or thereabout stepped to the ground.

"My nephew, Mr. Arthur Schuleman, Mr. Melvin," said Mr. Blackleigh. "Now let us get at this thing," he continued, 'but first first may I trouble you for a glass of water?"

They had been making their way over to the springhouse, near which were placed some chairs, and where Mrs. Melvin and Esther were working their butter.

"My wife and daughter, Mr. Blackleigh, and Mr. Schuleman. Esther, will you get these gentlemen a glass of water?"

Mr. Blackleigh smiled as he received the glass from the young girl's hand, but after he drank the delicious, cool spring water he said heartily, "Oh, my! but that's fine! A spring of water like that in Chicago would be worth a fortune. How I wish I could have a bottle of it on our table every day!"

Esther, pleased, handed him another glass of the precious spring water, which he took and drank with as much relish and appreciation as before, then said:

"Why don't you sell that water, young lady? Why," turning to Mr. Melvin, "you could in time make more than your insurance policy. You could indeed. Don't you say so, Arthur?"

That young man had taken the glass from Esther, thinking that he had never in his life seen a sweeter face. The sparkle of the water was brilliant, but not so attractive as the sparkling eyes of the young girl. Recovering himself from a moment's reverie, he smiled at his uncle's enthusiasm, but his face grew grave as his experienced taste detected the value of the water which had just satisfied his thirst. 'I am inclined to think it will prove valuable to you, Mr. Melvin," was his serious answer. "If you do not mind, I will take a sample of it with me to the city, and I hope to be able to give you a favorable report very soon."

"Mr. Schuleman is a chemist," explained Mr. Blackleigh to the astonished farmer. "But come, let us settle the question of this insurance. There'll be more of this later."

As the two men turned away, Mr. Schuleman turned to Esther and her mother, who had been attentive listeners, and said:

"Now, Miss Melvin, if you will procure a bottle, we will fill it with some of this delightful beverage, and I will

have it analyzed as soon as I return to Chicago. My father is an expert, and I follow in his footsteps as nearly as I can."

Shy little Esther blushed as she gave him the required receptacle, but they were soon conversing easily and were rapidly becoming acquainted, while Mrs. Melvin asked eager questions and received encouraging replies. In a short time the two strangers bade goodby to the Melvins, and needless to say, left the family highly encouraged as to the future.

Esther ran to tell the interesting news to Ralph. He at once said: "I know; I have read of the bottling works at the mineral springs in Colorado. But that water is used for medical purposes, and tastes horribly. I suppose the kind that comes from Germany is just as bad. Come, let's go and see what father thinks of the scheme."

Mrs. Melvin had placed her crock of half-worked butter in the trough inside the springhouse and was saying to her husband in anxious tones: "Oh, John, about how much would the water be worth? And how could we manage it? Wouldn't it be as warm and tasteless as rain water by the time we could haul it seventeen miles or more in the hot sun?"

"Why, yes; of course it would," said John, answering the last question first. "But you see, people in the city who would buy it keep ice, and they would only need to place the bottles which we would deliver to them in the refrigerator and in an hour or two the water would be as deliciously cold as ever."

"Just think," said Esther, "how many bottles we would require?"

"Why, Esther, not so many as you would at first think. We would do like the milk venders, arrange for our customers to give us back the bottles to be used the next time," said Ralph.

"Papa," said Esther, "I am just dying to begin! When may we?"

"I think," was the answer, "we'd better wait for Mr. Schuleman's report. I am to meet him at his father's office the day after tomorrow, when I go to the city to get this check cashed. If the water in that spring proves to be as valuable as those two men seem to think, we certainly have a fortune in it. Why, a company could be formed and a fine sanatorium built instead of the modest story and a half dwelling upon which we had planned."

'Just think, dear," said Mrs. Melvin, "how even that fire which destroyed our home may prove the greatest blessing which the good Lord could have sent us!"

"It may be so, it may be so," was the answer.

Needless to say the whole family anxiously awaited the return of Mr. Melvin from the city on the next day but one following the agent's visit to the farm.

"Well, father, what's the news?" asked Ralph, who met his father at the farm gate.

"Pretty good, my boy; pretty good!" answered his father, full of enthusiasm. "They say it's no wonder we have never had any sickness of any kind, and that our complexions are so clear, as our spring is a fine health preserver. I have purchased two hundred half-gallon bottles for ten dollars of the insurance money. You and Esther may wash and fill half of them leaving the remainder to be filled and taken on the second journey, when you collect the first ones after the manner of the milkman."

They were up early on Thursday morning, just one week after the fire.

"Now, Esther, we said we would start promptly at four o'clock," said Ralph, with all a boy's impatience, as he placed the last four bottles in the wagon, each one being carefully protected from the other by strips of bed quilts which had been damaged the week before.

Esther had lingered just a little to give her hair a few extra touches, and then the ribbon around her neck had to be arranged and rearranged before it suited her fastidious taste, for she was very neat and careful, this sixteen-year-old country girl, and she turned her face away from the glass that she might not see her own blushes as she remembered Arthur Schuleman's friendliness toward her. But this morning her bed had been one corner of the hay loft, and her dressing table a big corn box turned over on its side, so she was compelled to do the best she could.

But they were finally started.

"God bless their dear hearts," said John to his wife. "Carrie, we have two of the dearest children in the world."

She smiled and cried both at once as she said to herself, "Yes, Esther will be getting married before long and going away from us, my dear little girl!"

"We'll go first to Mr. Blackleigh's, on Wabash avenue," said Esther. "You know he told father if we were there by eight o'clock he'd not be gone to his office."

It was almost half an hour before eight o'clock when Esther rang the door bell at the number given her by their new friend. She felt her courage slipping away, but was reassured by seeing the gentlman himself appear at the door.

"Good morning, Miss Melvin. Come right in. You don't ever tell me you have driven all the way from the farm this early? Jane, tell Mrs. Blackleigh to come here."

Before many minutes Esther, quite at ease, was writing several names and addresses in the book with which she had been supplied for the purpose.

The Blackleighs took three bottles, for which they paid her thirty cents, and promised to be regular customers for a like amount every day through the summer, and told them of many of their friends who would do as well.

"Just say to your father that Mr. Schuleman and I will soon drive out to see him in regard to a business proposition which will be sure to interest him." Mr. Blackleigh was saying to Ralph as Esther passed down the steps and was assisted by her brother to her seat in the spring wagon.

It was a long, tiresome, but most successful day; and that night two happier young people than Ralph and Esther would have been hard to find.

But the water sending proved to be of short duration, for the Melvin sanitarium turned out to be a reality. The old spring, with its sweet waters brought a fortune to its projectors. Two young people whose names need not be mentioned, are in control of the institution, and have entered into a partnership for life.—American Farmer.

Nordy—Did that summer resort have all the comforts of home?

Butts—Not quite; but it made up for that in another direction.

Nordy—How's that?

Butts—It had all the discomforts.—Louisville Courier-Journal.

Cookery Recipes

Corn-Fritters.—To one pint of green corn scraped from the cob add one large tablespoonful of butter, one teaspoonful of salt and one of black pepper, one egg well beaten with one half pint of milk, and flour enough to make a thin batter. Bake on a hot griddle until a light brown, and serve very hot.

* * *

Cauliflower With White Sauce.—Carefully wash your cauliflowers, and boil them until tender in water with salt and one tablespoonful of butter. When done, lay them in a dish, and arrange the leaves in such a manner as will give them the appearance of one large cauliflower. Pour over them a white sauce, made as follows: Rub one-fourth of a pound of fresh butter with one tablespoonful of flour, a little salt and pepper and one small cupful of warm water. Set it over the fire until it is well mixed, but do not let it boil. Remove from the fire, and add the juice of a lemon, a little chopped parsley and a little grated nutmeg. If a thick sauce is preferred, add the beaten yolk of an egg.—Woman's Home Companion.

* * *

Fritters.—One pint of thick stewed tomatoes, half a cupful of sweet milk, two well-beaten eggs, half a teaspoonful each of salt and baking powder, and sufficient fine stale bread crumbs to make a rather thick batter. Mix thoroughly, and drop in spoonfuls on a hot buttered griddle. Brown delicately on both sides and serve hot. These are very nice served with syrup, or if seasoned with salt and pepper are also excellent served with meats.

* * *

Digestible Onions.—Cut onions in thin slices and cook in plenty of water until tender. Then drain and return to the fire with ½ cup water, salt to taste, ¼ cup vinegar and 1 tablespoon sugar. Let all cook together 5 minutes, then drain again and serve. Onions cooked in this way are extremely digestible and are enjoyed by those who find their after effects objectionable in any other form.

* * *

Walnut Sandwiches.—Chop one cup of English walnuts fine; scatter over them a little salt, then mix with sufficient cream cheese to make a paste. Butter thin slices of whole wheat bread, spread with the mixture and cover with another slice of the bread. Cut in fancy shapes and keep covered till wanted.

HOMELY HINTS.

One often hears complaints that the wash-house boiler rusts and iron molds the cloths. This may be easily prevented by rubbing the boiler directly it is emptied and while still warm, with any good household soap. Give it a good coating of soap, for the soap will not only prevent rust, but will help to make the suds when the boiler is filled for the next washing day. When damping clothes use hot water. It damps the clothes more evenly than cold.

A cement made by adding a teaspoonful of glycerine to a gill of glue is a great convenience in the kitchen and is especially good for fastening leather, paper or wood to metal.

The cleaning of greasy pots and pans won't be near such a disagreeable job if you will first stir around in them a handful of corn meal to absorb the grease.

Always keep the broom standing "business end up" or hanging up. It will last twice as long.

VETERINARY DEPARTMENT

BY DR. W. J. OLIVER,
318 East Second St., Los Angeles.

To the end that this department may be made as valuable to the subscribers as possible, we ask observance of the following: Be sure to state in full the history of the case, location of the disease and the conditions under which the animal has been kept just before and since the disease ap eared. Give your name and address, which will not appear in the paper if you so request. No charge whatever is made for such questions as are answered through the colums of the Cultivator, but when an immediate mail answer is wished Dr. Oliver asks an additional fee of $1.00 and will give immediate attention and reply by mail. In such case write Dr. W J. Oliver, 318 E. Second St., Los Angeles, Cal.

Questions should be in by Monday to be answered in the following Friday's paper.

GARGET.

Editor Cultivator: I have a cow that has been giving bloody milk out of one front teat for about ten days. It gathers between milkings and forms hard lumps of blood in the lower end. It does not appear to be sore, and there seems to be no inflammation.—Mrs. J., Bakersfield.

If there is no inflammation the principal treatment will be to keep the affected teat well milked out. If not possible to do so by hand, use the milking tube. The cow may also be given a tablespoon of nitrate of potash once each day for four days.

TO GROW POTATOES FOR SEED.

The potato seed is very much like the tomato in character, and in fact, is a very close relative of the latter botanically. The seed should be removed from the pods and washed to remove as much of the fleshy tissue as possible, then dried exactly as you would tomato seed, and stored until next spring. The young plants are quite delicate, and it is advisable to sow the seed in a window box as you would early tomatoes, and then transplant them to the garden later. It requires about three years to grow a good sized tuber from seed. From a commercial standpoint it is impractical, of course, to grow them in this way, though it is very interesting work for the amateur, as by this method one frequently secures something different, and there is a possibility of its being a new variety that will prove superior to the old sorts.

Cocoanut Meal 1.55

San Francisco Markets.

San Francisco, September 27, 1905.

Dairy.

While butter has advanced a cent or more a pound, the demand at present is very quiet and there is not much life in the market; most operators are pursuing a hand to mouth policy in placing orders. As a rule, the better offerings command top quotations, but the lower grades are often shaded.

BUTTER—Per lb:

Creamery, fancy .....27 @28
Do, good to choice .....25 @26
Dairy, choice .....23 @25
California Storage .....23 @25
Eastern Creamery .....22½@24
Eastern ladle .....20 @21

CHEESE—Per lb:

California Creamery, mild, new, extra .....13 @14
Do, choice .....11 @12
Young America .....13 @14
Eastern .....15 @17

Eggs.

Strictly fancy ranch eggs are very scarce and quickly picked up at top quotations. There has been a very strong advance during the week. Notwithstanding this, the greater number of buyers show a preference for storage grades, which command full quotations.

EGGS—Per doz:

Ranch, good to fancy ....36 @39
Ranch, selected large .....40 @41
California storage ..... 25 @28
Eastern, extra 26
Eastern, firsts .....23 @25
Eastern, seconds .....20 @21

Poultry.

POULTRY—Old Roosters, per doz., $4.50@5; young Roosters, $5.50@6, Fryers, $3.50@4.50; Broilers, $3@4; Hens, small, $4.50@5; large, $6@7; Live Turkeys, per lb., 21@23c; Spring Turkeys, 24@25c; Ducks, old, $4.50@$5.50; young, $4.50@6; Geese, per pair, $2; Goslings, $2.25@2.50; Pigeons, per doz., old, $1.25@1.50; young Pigeons, $2@2.25.

Fresh Fruits.

Apples—Per box, fancy, 90c@$1.35; common to choice, 40@75c.

Figs—Per box, Black, 50c@$1, as to size of package; White, 35@50c.

Pears—Per box, Bartlett, 75c@$1.75; other varieties, per box, 35@75c.

Peaches—Per small box, 65c@$1; carrier, 60@75c.

Table Grapes—Per box or crate: Seedless, 75@90c; Muscats, 50@85c; Cornichon, 75@90c; Blacks, 35@60c; Tokays, 65@85c; Isabellas, 75c@$1; open boxes, 75c@$1.25, as to variety.

Wine Grapes—Per ton, Zinfandel, $25@30; Mission, $20@24; White, $18@22.

Prunes—Per box or crate, 75c@$1.25.

Pomegranates—Per box, 75c@1.50.

Plums—Per box or crate, 40c@$1; open boxes, 75c@$1.25.

Quinces—Per box, 50@60c.

Cantaloupes—Per crate, $1.25@2; Watermelons, per doz., $1.50@3; Nutmeg Melons, per box, 50c@$1.

Blackberries—Per chest, $2.50@$3.50.

Raspberries—Per chest, $4.50@7.00.

Strawberries—Per chest, Longworths, $4.50@6; large varieties, $3.50@5; Santa Clara, $4.50@6.

Cranberries—Oregon, per box, $3@$3.25.

Citrus Fruits.

Citrus Fruits—Per box: Oranges, Valencias, $3@4.50; Lemons, $2@4.50; Limes, $5@5.50; Grape Fruit, per box, $1.75@2.75.

Vegetables.

VEGETABLES—Tomatoes, per box, 25@65c; Green Peppers, per box, Chile 25@50c; do, Bell, 25@50c; Okra, per box, 35@50c; Beans, per lb. green 2@2½c; do, Wax, 3@4c; Lima, 1½@2½c; Garden Peas, per lb., 3@4c; Cucumbers, per box, 35@50c; Summer Squash, per box, 35@50c; Egg Plant, per box, 35@50c; Garlic, per lb., 5@5½c; Green Corn, per sk, 50@$1, per crate, 75c@$1.25; Marrowfat Squash, per ton, $15@20.

POTATOES—Per ctl: River Burbanks, 50@70c; Salinas Burbanks, 75c

@$1.15; Early Rose, nominal; Garnet Chile, nominal; Sweet Potatoes, Merced, $1.40@1.55.

ONIONS—Per sk, Yellow, 60@75c.

Dried Fruits.

DRIED FRUITS—Prices for carload lots, f. o. b. at California common shipping points, in bags, are per lb, as follows:

Apples—Evaporated, fancy, 7¾@8c; choice, 7¼@7½c; standard, 6½@6¾c; Sun Dried, nominal.

Peaches—Crawford, fancy, 9c; choice, 8¼@8½c; standard, 8c; Muirs, fancy, 9½@10c; choice, 8½@9c; standard, 8¼c.

Prunes—Sack basis, f. o. b. For boxed goods add ¼@½c; four-size basis, 3½@4¼c; old crop, 2¾@3½c.

Pears—Bartlett, unpeeled halves, fancy, 12c; choice, 9@10c; standard, 7½@8c.

Apricots—Royal, fancy, 9½@10c; choice, 7¾@8½c; standard, 7¼c; Moorpark, fancy, 12c; choice, 8½@10c.

Figs—Per lb., White, 10-lb. bxs, fancy, 60c; choice, 55c; standard, 50c; Layers, 50@65c; bulk, fancy, 4c; choice, 3¼c; standard, 2¾c; ungraded, 3½c.

RAISINS—Prices per lb, f o b Fresno, are as follows: Bleached Thompsons, Seedless, extra fancy, 10½c; fancy, 9c; choice, 8c; standard, 7c; Bleached Sultanas, fancy, 7c; choice, 6c; standard, 5½c. Prices are for 50-lb cases, f. o. b. disccunt of 1½ per cent for cash.

Honey and Beeswax.

HONEY—New crop, Comb, per lb., 10@12c; Extracted Water White, 6c; Light Amber, 5@5½c; Dark Amber, 3@4c; Hawaiian, 2@2½c.

BEESWAX—Per lb, 26@28c.

Hops.

The price of desirable old crop is nominal at 12@14c per lb., according to quality.

Beans and Seeds.

Arrivals of beans are steadily increasing and the market continues in an unsettled state, with buyers generally holding off in anticipation of lower prices. The quoted rates are largely nominal and little business of importance is passing at present.

BEANS—Prices per ctl. for choice selections of new crop stock: Large White, $2.25@2.60; small, do, $3.25@3.50; Pea. nominal; Limas, spot, $4@$4.25; October delivery, $3.25@3.75; Red, nominal; Pink, $2.15@2.50; Bayos, $3.10@3.50; Blackeyes, $3.50@4; Red Kidneys, $3.25@3.75; Horse Beans, $1.25@1.75.

DRIED PEAS—Prices per ctl: Niles, $2@$2.25; Green $2.25@2.50; Field, $1.75@2.25.

Live Stock.

CATTLE—No. 1 Steers, 6½@6¾c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5½c; second quality, 4½@5c; third quality, 4c; thin Cows and Heifers, 3@4c, Bulls and Stags, 2@3½c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4¼@4¾c, gross weight; medium, 3¾@4c; heavy, 3½c gross weight.

SHEEP—Per lb: Wethers, No. 1, 3¾@4¼c, gross weight; Ewes, No. 1, 3¼@3¾c, gross weight.

LAMBS—Suckling, $2.75@3.25 per head or 4½@5c per lb., live weight.

HOGS—Per lb.: Hard grain fed, weighing alive 80 to 130 lbs., 5¼c; 130 to 250 lbs, 5½c; 250 to 350 lbs., 5¼c; rough heavy, 4@4¼c; common, 3½@4c.

Hay and Feedstuffs.

HAY—Per ton: Wheat, $10@14.50; Wheat and Oat, $10@13; Oat, $6.50@12; Barley, $8@11; Clover, $7@10; Alfalfa, $6@9; Stock, $5@6.

FEED CORN MEAL—Choice grades, per ton, $30@30.50.

STRAW—Good to choice, per bale, 30@50c.

FEED—Mixed Feed, per ton, $23@24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $23@24.

CRACKED CORN—Choice stock, per ton, $30.50@31.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $26.50@29.50.

GROUND BARLEY—Per ton, $22.50@23.50.

COCOANUT CAKE—In lots of 10 tons, $20.50; 5 tons, $21; less quantity, $21.50. Prices are mill rates and are subject to change without notice.

Flour and Cereals.

FLOUR—Net cash, Family, Extra, $4.80@5.10 per bbl; Baker's Extra $4.70@4.90; Oregon and Washington, $3.80@4.60.

WHEAT—No. 1 Shipping, per ctl., $1.30@1.35; inferior grades, $1.15@1.30; White Milling, good to choice, $1.35@1.45 for new and higher for old.

BARLEY—Choice No. 1 Feed, $1.03¾@1.07½; some fancy grades up to $1.08¾; common to fair, $1@1.02½; inferior grades, 90@97½c; Shipping and Brewing, $1.10@1.12½; Chevalier, $1.10@1.20.

OATS—Good to choice White, $1.37½@1.45; Red, $1.35@1.45 for choice to fancy; $1.15@1.32½ for common to fair; Black, for seed, $1.50@$1.65.

RYE—Good to choice, per ctl., nominal; new, $1.45@1.52½.

CORN—Good to choice, per ctl: California, new, large Yellow, $1.42½@$1.45; small do, $1.60@1.65; White $1.40@1.42½; Eastern, Yellow, $1.42½@1.45; White, $1.42½@1.45; mixed, $1.40@1.42½.

CITRUS MARKETS

There is but little interest in the orange market during the last week and the offerings are very light, and quality is indifferent. There is enough demand, however, that occasional cars of fancy stock command reasonably large figures, but the higher offerings now seldom reach above $5 to $5.50, while the average is more liable to remain in the neighborhood of $4.

Lemons likewise show less interest than formerly though good prices are secured, compared with those of former years. The $7 and $8 prices reached a few weeks ago are now not touched at all, the range being generally between $4 and $5.

New York.

Only a car of oranges was offered at Tuesday's sale, the highest price being secured for fancy Mountain Valencias at $525. Two cars of lemons were sold, commanding from $3.50 to $5.

Quotations: Mountain, fy, Nordhoff, $5.05; Mountain, ch, Nordhoff, $4.30.

Lemons—Quail, xc, O K F Ex, Upland, $4.70; Coyote, ch, OKF Ex, Upland, $4.05; Fox, xc, OKF Ex, Upland, $4.30.

On Wednesday four cars of Valencias were offered, being mostly good stock and commanded, if anything, rather higer prices than the former day. This, notwithstanding quite liberal offerings of Jamaica fruit, which does, not, however, compete with California stock, being picked up for the cheap peddlers' trade.

There were two cars of lemons offered, selling quickly for $3 to $6, some extra fancy Rialto fruit commanding the latter figure.

Valencias, Old Mission, fy, Chapman, $4.25; Purity, xf, Orange, $5.70; Bridal Wreath, fy, Wilson, Orange, $5.25; Ruby, fy, Spruance Upland, $4.65; Seal of California, st, Spruance, Upland, $3.00.

Lemons—Ocean, xf, Rialto, $5.60; Fountain, fy, Rialto, $4.75; Crocker-Sperry, ch, Montecito, $3.80.

Boston.

No oranges whatever offered on Monday, but two cars of lemons met with strong demand and good prices. The range was from $2.80 to $5.90 per box.

One car each of Valencias and lemons were offered on Wednesday. Market was exceptionally strong on lemons and oranges showed an advance over previous offerings.

Lemons ranged from $4.30 to $5.55 and Valencias from $2.90 to $4.95.

CITRUS SHIPMENTS.

Total shipments of citrus fruits, since November 1st, 1904, were 29,555 of which 4212 were lemons.

CLIMATE AND CROP REPORT

The weather and crop conditions for the week ending September 25 are reported as follows by Section Director McAdie of the Climate and Crop Service, San Francisco:

General Summary.—The weather continued generally clear and warm most of the week, with high temperature on the 21st and 22d and cooler weather at the close. Light showers fell in the northern coast sections and thunderstorms accompanied by rain occurred in the southern section on the 22d and 23d. The rainfall in the southern mountains is reported very heavy.

Grapes and raisins were somewhat damaged by rain in San Bernardino county and other portions of the south, but no injury was done to the raisin crop in San Diego county. Raisin making in the San Joaquin valley is progressing rapidly and some of the raisins are going to packing houses. The crop is turning out rather better than expected. Wine and table grapes are yielding an excellent crop in many places. Wineries are running in all sections and heavy shipments of grapes are being made. Almond harvest in the San Joaquin valley is nearly completed and the crop is good. Walnuts are nearly ready for harvest; the nuts are well filled, but the crop will be below average in most sections. Prune drying is nearly completed; the yield is below average, but the fruit is of excellent quality. Oranges are in good condition in all sections and one of the largest crops on record is expected. Apples are in unusually good condition and will make a heavy crop.

Hop picking is almost completed and baling is well under way; the crop is about average in yield and quality. Harvest is progressing on beans and sugar beets. The wheat crop in San Benito county is better than expected.

Eureka Summary. — Considerable fog along the coast, but weather generally favorable. Thrashing is about finished; the yield of oats is exceptionally good. Interior grass is very dry and the flow of milk has decreased. Moderate shipments of apples.

Los Angeles Summary.—Showers Friday did neither good nor harm. Grapes are well ripened and going to winery. Celery is in fine condition and shipments have commenced. Bean thrashing continues.

BUSINESS NOTES

The Seattle Sunday Times devoted the first page of its magazine section in its last issue to a large portrait of Charles H. Lilly, president of the seed and poultry supply house of Chas. H. Lilly Co., Seattle, Portland and San Francisco. An interesting character sketch tells how Lilly, when 15 years old, on an Illinois farm, determined to be "somebody." That determination, says the Times, was the keynote of his success. The progress of this farm boy, and the growth from the humblest of beginnings of the business institution he established, are vividly told by the Times. Both the story and the manner of the telling tend to make the article a stimulus and an inspiration to an ambitious young man on a farm today.

THE FENCE THAT SELLS.

We are printing in another part of this issue a very attractive advertisement issued by The American Steel & Wire Company, manufacturers of American Fence. It is headed American Fence Talks by the makers, and sets forth some very interesting statements.

The American Steel & Wire Company are very progressive and up-to-date, and they have every facility for turning out the best fence that it is possible to manufacture.

With their immense capital—which enables them to manufacture American Fence all the way from the digging of the ore out of their own mines into the finished product—surely puts them in a position to offer a reliable fence at the very minimum of cost.

Read carefully the advertisement of the American Fence in this issue; you are safe in buying a fence that is so well manufactured and sold by such a responsible concern.

If you don't find a dealer in your own town that handles this fence, we suggest that you write The American Steel & Wire Company direct and they will send you a catalogue and direct you where you can get their fence. Their address is The American Steel & Wire Company—your letter should be sent to their nearest address to you—Chicago, Denver, New York or San Francisco.

Experiments with Inoculation of Seed

In California Produce Excellent Results. Interesting Paper on the Subject by J. Allen Osman, Whittier

I believe I was to give you a report of a series of experiments that I have been carrying on in reference to forage crops, and in compliance with the above promise. I beg leave to give you the following results of experiments carried on at my home place, Ventruilla Ranch, Rivera.

In the fall of 1903 I sowed Canadian peas on 24 acres of walnut orchard. This ground had never, to my knowledge, been planted to peas before. In the spring of 1904 I turned this crop under and so far as I am aware there was no special improvement noticeable in the crop, although the crop that year was much larger than the preceding year, but I could not ascertain that there was any appreciable difference between the crop on this ground and that on my neighbors.' In the fall of 1904 I sowed this same 25 acres again with peas. I also sowed another field of 20 acres in peas and another piece of 5 acres. Neither of the last two mentioned had ever had peas sowed on them to my knowledge. I sent to Washington for some bacteria to inoculate the seed. I sowed probably what would be an acre of the first 25 acres which was sown the year before. Note carefully, please, the results. In the spring of 1905, just prior to plowing this under, I pulled up from various parts of the field, roots. Where the seed had been inoculated there was a line of demarkation which was as plain and distinct as a curb line on a street. Within the zone of the inoculated soil the roots were covered with nodules as thick as they could possibly stick. Outside of this zone where the peas had been the year before the roots had quite a number of nodules, but not as large nor as many as where the ground had been inoculated; whereas in the two other fields where peas had never been sown before there were only rudimentary nodules and not very well defined. Under a glass they could be discovered but they were not prominent or well defined to the naked eye. I have a place in this orchard, which I will designate as No. 1, sown in the fall of 1903, in which there has been a wash-in of white sand and there are four or five walnut trees which grew well until they were about six years old and for the last three years there was no appreciable growth prior to this year. The fruit on the trees dried up and dropped off and the trees looked as if they were well-nigh their end. I was going to remove them when it occurred to me that these trees offered a most excellent opportunity for experimentation. I could see no appreciable difference in the trees last year, but this year (and, by the way, they are within the zone of the inoculated seed) I could discover that they have grown very materially and they have a reasonable amount of fruit upon them which they have matured. In this bunch of poor trees two trees stand outside of the inoculated zone and they have not done as well as those within the above described limit. Whether this is a mere coincidence or not, I leave it to the reader to judge. I am convinced that by continuance of this method of green forage that we will bring those trees back again to vigor. The reason I think so is because formerly this particular part of the orchard was good ground, but being in a sort of arroyo the sand washed in in one of the floods which visited California some years ago. There are about three feet of good soil, then about two and a half or three feet of this white sand when we again strike good soil. My thought is by a series of experiments to determine whether by fertilization we can force the roots down through this sandy strata and find feeding ground below. I think we can draw the following conclusions from the above narrative: That inoculating the seed produces immediate results; secondly, that where peas have been sown the year before that inoculation takes place the second year but not to so marked a degree as where the seed is inoculated; and thirdly, that the first year where peas are sown inoculation is not of much benefit; that the benefit would be the same as any green forage turned over, but it prepares the ground for inoculation of the subsequent crops; that the results to the growth of the tree and to the fruit bearing qualities are no doubt vastly enhanced and that the nitrates given to the ground by this method of culture will be of great benefit to the walnut industry. I have no doubt but that many men have observed these same things, as above narrated.

* * *

In an extended review of his experiments with alfalfa bacteria, A. D. McNair in Farm and Ranch writes that "the Pacific states seem to have an abundance of alfalfa bacteria as is proved by the fact that the nodules are found on the alfalfa root in all these states. On the slopes east of the Rocky Mountains there is also a good supply of these bacteria, but when we reach Eastern Kansas and Nebraska they become less frequent or are not found at all. From the longitude of eastern Kansas to the Atlantic ocean it was supposed, until two years ago, that alfalfa bacteria were present only in the rarest instances; but thanks to the researches of Prof. Hopkins of Illinois, we now know that the bacteria of melilotus or sweet clover, is practically identical with alfalfa bacteria and that where melilotus grows wild along road-sides and creek banks, the land is already inoculated with alfalfa bacteria.

It has been proved by many experiments that if alfalfa bacteria are not in the soil they may be put in by artificial means and the process of putting them in is called "inoculation."

Soil may be obtained from a field which already has the bacteria and may be scattered on the field which is to be sowed; or, "pure culture" bacteria may be obtained from companies who deal in them with full directions how to use them. If the soil itself is inoculated it is called "soil inoculation." If the seed is inoculatd it is called "seed inoculation."

Much testimony has been collected by the United States Department of Agriculture and by private companies showing that farmers have gotten excellent results by inoculating with the pure culture bacteria. My own experience with them was not good, but with soil from an old field it was good. I find, also, that such authorities as Prof. Hopkins of Illinois, and Joe Wing of Ohio, are more favorably impressed with the old method than with the pure culture method. In using soil from an old field I think it is safer to drill it in the ground than to scatter it broadcast where the bright sun shines on it, for bacteria "love the darkness better than the light." As regards quantity, I think that from 100 to 500 pounds of soil should be used per acre.

There is a widespread belief that alfalfa bacteria are the same as cowpea bacteria and that if the land has grown cowpeas it is thereby inoculated for alfalfa. I do not believe that this is the case and I will offer as evidence a leaf from my own experience.

On the experiment farm at Southern Pines, N. C., I found that cowpeas, violet beans, soy beans and peanuts each and all had nodules on their roots, whether planted on one part of the farm or another, proving conclusively that the soil was naturally inoculated by these legumes. When, however, I sowed alfalfa, crimson clover and hairy vetch on the same land I found no trace of a nodule and it was only after alfalfa was inoculated with alfalfa soil, clover with clover soil and vetch with vetch soil that nodules appeared on these legumes. Surely if cowpea bacteria are the same as alfalfa bacteria I ought to have gotten alfalfa nodules on land which had previously grown cowpeas, and which had cowpea bacteria in abundance. Facts, as I know them at present, seem to indicate that the bacteria of any legume may be used to inoculate only when the two plants are very closely related, as is the case with alfalfa and sweet clover, which are indistinguishable in the early stages of their growth, or as is the case of peas (English peas) and vetches, which latter are often called "wild peas."

* * *

Another popular belief is that stable manure contains alfalfa bacteria and that if land is dressed with such manure it is thereby inoculated. I find that this view is favored by Mr. Wing of Ohio, and I hesitate to oppose him on anything pertaining to alfalfa, for I know how well posted he is on the subject. Neither would I do so were it not for the fact that I previously entertained the same opinion and changed my mind as the result of an experiment which I made while superintendent of the experiment farm at Southern Pines, N. C. I felt so sure that manure would inoculate the soil that I waited expectantly to see the alfalfa grow on two plots, one of which had cow manure on it and the other a heavy dressing of manure from the horse stable. I was doomed to disappointment in both cases, for after examining a great number of plants I reluctantly came to the conclusion that the manure had no effect on nodule development.

One plant out of, perhaps, a thous-

California Horticulturally

By John Isaac, Sacramento, Cal.

IT IS BELLEFLEUR.

What is palpable has been made plain, and after much argument and due consideration of authorities it has been decided that a Bellefleur is a Bellefleur. The fact that the word has been corrupted from its original form and meaning into "Bellflower," is not considered and this, one of the best of our apples, is to be allowed to continue under its original name. The apple originated in France and was given a French name descriptive of its character, which was "Bellefleur," or beautiful flower. This meant something, but its corruption into the Anglicised "Bellflower" destroyed its descriptive meaning. We are pleased to note that Prof. Wickson has taken a stand for the original and correct name of this apple and declares in favor of "Bellefleur." So it was named and so it should remain.

* * *

A VERY DESIRABLE NEW FIG

A new fig has been reported from Kern county, which if it has all the good qualities claimed for it, is certainly a very desirable addition to our horticultural products. The fruit is a seedling grown by R. M. Dodge, and it is claimed that it has very superior shipping and keeping qualities; that it may be picked ripe and shipped for great distances without souring or decaying. At the same time the fruit is of good size, plump and of very superior flavor. A ripe fig is usually a very poor shipper, as it is soft, soon sours and falls down and cannot be got to market, if the market is any distance, in any usable condition. To appreciate figs they must be eaten when fully ripe and eaten direct from the tree. If Mr. Dodge has produced a fig which can be shipped for long distances and will reach market in prime condition, he has added enormously to the horticultural wealth of the State.

FUMIGATION WILL KILL GOOD AND BAD ALIKE.

I notice a statement in some of the papers of Southern California to the effect that while hydrocyanic-acid gas fumigation is fatal to black scale, it is harmless to the scutellista cyanea. It seems to me that that sort of fumigation must be very much like our climate—one which encourages all good things but is death to all the undesirable. For years I have heard the siren song that this pest, and the other, would not live in California because they would not be able to endure our climate; that it was perfectly safe to admit trees with all sorts of diseases—the peach yellows, rosette, etc., that scale pests of all sorts might be admitted because our climate would kill them, but we might rely upon it that all desirable things would thrive because our climate was just adapted to them. We have always maintained, and the facts have borne us out, that wherever a plant will thrive or grow, the pests and diseases peculiar to the plant will also thrive, and that it was a good deal easier to keep them out than to take chances on the climate killing them after we got them here. So, in the matter of fumigation, if it is worth anything for the killing of scale, it will prove fatal to all forms of life with which it comes in contact, and if the scutellista on a tree are found alive after fumigation, then that fumigation has been a failure. Where parasites are established in an orchard there should be no fumigation or spraying. The work of the parasites may be slower than that by artificial means, but it is more effective in the long run, but there is no earthly use of expecting results from parasites while they are being annually killed off by the application of deadly washes or poisonous gases. If you want results from parasites, don't spray or fumigate. If you have doubts as to the efficiency of the parasites, go ahead with artificial remedies, but do not think for a moment that you can use both at the same time, or that you can so fumigate that you will kill all the pests and not injure your friends.

* * *

A FAIRLY GOOD FRUIT CROP.

Some how or other we are never so bad off as we think. Our prophets are usually pessimistic and see the future in a dark cloud. Every spring we have a light frost, or almost every season, and there is usually a dropping of small fruit, and then we hear the cry that the entire fruit crop of the State is gone, or at least eighty to ninety per cent of it, yet when the season is over and the returns all in, we always come out with the usaul average, with slight fluctuations, it is true. It is largely so the present season. There has unquestionably been a short fresh fruit crop this season, and a very short one too, but in spite of that fact our shipments of fresh fruits from the northern counties will exceed those of any former year by some hundreds of car loads. The canneries will put up a smaller pack of some varieties, especially peaches and pears, yet there will be a very fair pack of canned goods, and the market will not suffer. We are now hearing about the great shortage in the prune crop, but it is quite safe to predict that we shall produce more prunes than we can dispose of at fair figures, and the same is true of raisins. There has been a shortage in many varieties of fruit this season, in fact, it has been the poorest fruit season for many years, and yet there is still enough to get along with, and the predictions of the prophets have failed again.

WORTH TRYING.

Grape growers in the United States may derive a useful hint from a process, as yet unknown on this side of the water, by which vine growers in France are enabled to market fresh outdoor grapes all through the winter. The method, which is a recent invention, is both curious and interesting.

Bunches of the finest grapes, when ripe in autumn, are cut in such a way that to each bunch a piece of the vine five or six inches long remains attached. From this piece the stem of the bunch hangs—an arrangement which, as will presently be seen, is essential to the success of the operation.

A large number of wide-necked bottles, filled with water, are ranged in horizontal rows on racks in the cellar, and in the open end of each of these receptacles is placed a bunch of grapes, that is to say, the pieces of vine stem is inserted into the mouth of the bottle, and the grapes hang outside. The grapes do not touch the bottle, but are supplied with moisture through the vine stem, which is immersed in the water.

In this manner Black Hamburgs and other choice table grapes are kept fresh and perfect through an entire winter. The temperature of the cellar, being uniform and moderately low, is favorable to the preservation of the fruit, and to compensate for evaporation water is supplied daily to the bottles. Naturally, such grapes are expensive, but there are plenty of people, it seems, who are glad to pay $2 pound or even a higher price for them.—Daily Hotel Reporter.

ALMERIA GRAPES.

The first grape boat for New York will leave this port about the 15th of September and others will follow in quick succession. The crop is said to be smaller than last year, although conservative estimates place the number of barrels at 1,500,000. The grapes appear to be in fairly good condition for transportation, smaller in size than last year's crop, but harder and sounder.

The "Trust" of 1904 has resolved itself into "La Associacion Frutera," but the objects are practically the same, viz: Accepting only the best and quickest boats, especially for America; fixing the rate of freight, and limiting the number of barrels for each, according to destination, those for New York being allowed to load 15,000 barrels.

I am informed that from 35 to 40 ships are expected for New York alone. The majority of these will be passenger steamers.—From report of A. E. Charleton, Consul, Almeria, Spain.

He (reading about the last society wedding)—They have a lot to say about what the bride wears, but they have nothing to say about the poor bridegroom.

She—They have no need to, because it is a well known fact that he usually wears a worried look.—Boston Globe.

Hints on Seed Selection

By J. C. Ostergard, Burbank, Cal.

The rancher who raises first class produce makes money. The rancher who raises second class produce makes a living. The rancher who raises third class produce makes a dismal failure.

* * *

Conditions for Success.—Conditions may be said to be numerous, but in my opinion the most vital ones are good seed, good soil, and good cultivation. This time of the year is most opportune for seed selection, of which I shall treat in this article. There is an idea abroad that for success, we must import seed. It is not strange that this notion should be as deep rooted as we find it. The seedman has proclaimed it, the ignorant and unscrupulous agricultural editor has backed it up. The fact of the matter is that some kinds of seed can be successfully grown in one locality, while the same seed, if raised under different climatic and soil condition, would produce an inferior seed. Many kinds of seed grown in California are superior or equal to the best grown anywhere in the world. There, is, however, some sorts, among which is cauliflower, cabbage, carrots, turnips, beets and radishes, the seed of which it is highly important that we procure from abroad. Never in the history of the world have we had fruits, grains and vegetables of such high quality and productive ability as today. These desirable results have been achieved only by the endless care and watchfulness of the skillful tiller of the soil. Nature wants seed but she has but a single object in view, namely, reproduction of her species. In everything it matters little with her if it contains little or nothing edible. No matter how much you improve, she has a general tendency toward first conditions. Hence, in order to maintain the high state we have arrived at, the most constant vigilance is imperative.

* * *

How the Standard is Maintained.—The honest seed grower selects from a field, seed of only the very choicest plants for his next year's seed crop. The balance is harvested and sold to customers who will not, or cannot, grow their own. While the seedsman has thus secured to himself the very choicest, yet all the seed sold was grown from the very choicest of the previous year, and will prove entirely satisfactory. Were the seedman to harvest and sell seed from only perfect specimens, seed could only be procured at fabulous prices. I have had watermelon seed that I would not have sold for five dollars a pound, and have refused one dollar for a single melon. If the seed grower takes the care aforementioned he does all that can be expected, but many do not, hence it is important for everybody to save his own where practicable. Be on the lookout for sports, that is, new varieties, as they appear from time to time. Make careful tests before you plant a whole field with them.

It is said that a Chinese emperor once watched a head of rice that was far in advance of the field. He marked the spot and kept careful watch until it was ripe, which occurred six weeks ahead of the rest of the field. The precious grains were guarded as though they were jewels. When planted in the Imperial garden a watchman guarded the little plot until harvested. That little head of rice extended the rice fields for several hundred miles northward, and was recorded by order of the emperor as the most important event in his reign.

* * *

Imported Seed.—When you buy seed you should know the kind of soil it is grown on, if it is rich or poor. To increase your yield and have a heavy, bulky growth the seed should come from poor soil, never procure seed from very rich land, for a thin soil, unless you want an improved quality and diminished quantity. If your soil is so poor that you know of no poorer, then select your own.

* * *

New Varieties—While scientists have done much toward this end, yet it is doubtful if all their efforts can match what has been accomplished merely by selection of sports as they appear from time to time. I will mention the Navel orange, the Eureka lemon, the Muir peach, the Phillips cling, the Logan berry, the soft shell walnut, the I X L, Ne Plus Ultra and the Nonpareil almonds, and the priceless Concord grape is yet another example. Thus it will appear that it is not necessary to be a wizard or a scientist in order to obtain new and invaluable fruits and plants. Let every boy and man keep his eyes open for new and better fruits and plants, but don't be too hopeful; be critical and don't expect that you have something that the men of affairs will tumble over one another for, just because it is new and there is nothing like it. It must have special merit either in producing more or be of better quality, or make a better appearance than anything in its line. White blackberry, for instance, is but a novelty, and it utterly fails as a boon to mankind in any sphere; the fact that it is white is but a negative virtue; nay, it is no virtue at all; that fact is sufficient to debar it from the markets, even though it otherwise was up to standard.

* * *

Ladybugs and Aphis.—If you see any vines having aphis, destroy them at once. You can expect a large number to hatch next spring from a small colony left over this fall. Ladybugs, the natural enemies of the aphis, need protection during the winter months. To this end nothing is better than a dozen corn stalks tied together and tied to trees head down. Or in the open, drive stakes in the ground and tie the corn stalks to them upside down. Our friends will keep dry during the heaviest storms and be ready for work next spring.

* * *

If you have a piece of land that needs invigorating, irrigate it now, do it well, and sow to Canadian field peas, plow under in the early spring and note results, which will be highly satisfactory.

Sometimes there are living beings in nature as beautiful as in romance. Reality surpasses imagination; and we see breathing, brightening, and moving before our eyes sights dearer to our hearts than any we ever beheld in the land of sleep.—Jane Austen.

Queries and Suggestions

PLANTING ALFALFA.

Editor Cultivator: Is it best to sow barley with alfalfa? Many do so, claiming that it helps to keep down the weeds.

What crop would you advise planting on land where chickens run? Would they disturb garden peas to any extent? We feed them Calfalfa and fresh kale every day so that they are not over hungry for green stuff. What variety of peas is best for field culture?—Subscriber.

Many do as you say, sow the barley with alfalfa in planting, but we think as a rule preference is given for the alfalfa to be sown alone. As you say, the extra crop helps to keep down the weeds, also prevents the ground from baking, but the fact that it also takes from the moisture and nourishment of the soil and prevents stooling, usually induces planters to sow the alfalfa in its own seed bed without the barley.

Your potatoes are a good crop where chickens are to run. Peas, likewise, would be, though it is possible you would have to keep the poultry off the field during the sprouting and early growing period. The Marrowfat is a good field pea. The favorite, however, in the southern part of the State is the Yorkshire Hero. Corn is a good crop to grow where poultry ranges, though, of course, in that case, the poultry must likewise be kept from the field during the early days of growth. When it gets higher they will not injure it. Either this or the peas are good crops to alternate with potatoes and leave the ground in good condition for potatoes next year.

VARIOUS QUESTIONS.

Editor Cultivator: Please advise me as to the best season and method of pruning cherry trees. 2. What is the best way to keep horses in good flesh while working? 3. What is the best food for breeding chickens? 4. What is the trouble and what is the remedy for peach trees when the new growth dies in early springtime? Afterwards the trees put on beautiful new growth. —H. A. F.

Your query regarding pruning has been referred to the Cultivator representative in the North and we hope to give a practical article on that line a little later. 2. To keep work horses in good flesh means clean stables, thorough grooming, washing of shoulders during the hot weather at least, clean, wholesome hay, preferably barley, if it does not injure the mouth, with reasonable amount of grain feed, which should always be decreased when animals are not working, and many other suggestions which may be seen in the stock department of the Cultivator in the issue of September 22d.

3. Read Mrs. Basley's article on feeding of poultry in former issues. 4. It's a trouble which prevails all over the State and for which no one has yet secured a remedy.

JOHNSON GRASS.

Editor Cultivator: I send you two samples of grass that annoy me. What are they and how can I get rid of them?—E. H. Elkin, Lompoc.

The green, thriftier-growing grass which you send is Johnson grass, a perennial which is one of the worst pests and yet is advised by some as an excellent stock food where it is once established in pasture. In orchards or along irrigation ditches, however, it is almost impossible to eradicate it. It propogates not only from the seed but by the root stalks which run underneath the ground, making new shoots at each joint, as they grow. About the only way to eradicate it is thorough cultivation, if it is on ground where it can be cultivated, or by grubbing out and continually keeping the green growth from ever appearing above the surface. Of course, it may also be killed by heavy applications of salt, but this "kills" the soil for any other crop.

The other dried grass which you sent was an annual, "wild rye." This is no such pest as is the other, in fact is a good stock food, but, if you do not wish it to be perpetuated, mowing before it goes to seed will in a short time kill it out.

DURUM WHEAT.

Editor Cultivator: I have seen somewhere a strong recommendation of "Durum wheat" as a drought resistant grain for our semi-arid section. I want to raise some wheat for chicken feed. Will this wheat have any advantages over other kinds for this purpose?

Also, has "Chevalier barley" any advantage over common barley for grain raising?—W. B., Dulzura.

Durum wheat has been grown quite largely in some sections of the Middle West. At the mills here, however, we are unable to get any information as to local trials with it. There are over 6,000,000 bushels produced annually in the United States and it has commanded a higher price than any other wheat. It is a good drought resistant, and we understand yields heavier than any other wheat. It is used largely in the manufacture of macaroni, but, we are told, has less of gluten than millers desire. Inquiry at the mills and seed houses in Los Angeles developed the fact that no seed is to be had here of this wheat. Doubtless it will make an excellent chicken food.

Regarding Chevalier, or beardless barley, it has been grown many years. It yields far less than the common bearded grain and seems more subject to smut and other diseases.

SOLANUM WENDLANDII.

Editor Cultivator: Can you tell me what is the matter with my Solanum Grandiflorum? It leaves out, blossoms and keeps shedding its leaves until it is perfectly bare. The leaves seem to curl and drop as soon as leaved out, and I find lice on leaves and have washed the vine many times with suds.—Mrs. C. A. Loud, Encinitas.

We presume you mean the Solanum Wendlandii, sometimes called the potato vine, a magnificent climber, with dark, glossy, green leaves with large-lilac blue flowers. Just what the trouble may be with your vines, it is hard to tell from the above description, as it might be caused by red spider, or by the aphis, or it might even be caused by drought or, at this season of the year, might even be shedding its leaves naturally, as it is a deciduous vine. If the aphis or spider have to do with the dropping, it is possible spraying with a solution of distillate, at the rate of two gallons of distillate to one hundred gallons of water may prove a good remedy.

San Francisco capitalists have taken samples of sand from the Yuba river at Marysville and if the tests prove right they intend to manufacture glass and lime bricks at that place.

Outlook for Citrus Industry

The getting of exact prices or, better, of average prices, from any one section is an impossibility. It is comparatively easy to get the big figures where a grower has done exceptionally well, and, with some of the co-operative associations averages may be secured, but to attempt to secure averages from an entire community brings one up against a very hard proposition. If one goes to the individual grower who has been disappointed in the season's returns, he will find great backwardness in coming forward with returns. This is occasioned to a certain extent by the strife between co-operators and independents and the following of the Citrus Union. At one time the associations were not as strong as now and made annual campaigns for new members, and this sometimes occasioned more or less feeling between neighbors on account of the difference in opinions as to the best methods of marketing. But it goes without saying that the man who gets big returns "doesn't whisper it down the well but climbs a tree and hollers." When it is understood that there are seventy-five hundred of these growers in California, it may be seen that there will be some diversity of opinion.

The California Fruit Growers' Exchange will net this year for all oranges something over $500 per car. No other large shipping agency which we have approached keeps their records in such a way as to give this information out, or, if they do, withhold the information. In fact, no other method of marketing takes into account so many people as does this. In fact, there is more of an independence between grower and shipper with the other systems than with the Exchange, so that there is no call upon them or other shipping agencies to make known the entire transactions as there is with the Exchange which is purely co-operative, every official being subject to the will of the members to whom he must make report. This has objections in that the publicity required by the members has sometimes been an embarrassment to the management. There is sometimes even an unreasonable demand on the part of the grower that he shall know all the ins and outs of the business when consideration of the fact that these business secrets thus open to public inspection weaken the management to a certain extent in its ability to control the business. But it is one of the weak points to co-operation which is more than overcome by many strong ones.

As to the different localities, it is, as we noted before, a year somewhat different than heretofore, for the greater prices of Valencias which are more generally grown toward the ocean give a higher average to these shippers than to those in the inland valleys where the finest of Washington navels are produced. While one association, the name of which we will not mention, secured only a little over fifty cents per box for its choice grade regular size fruit, it received a most satisfactory price for its Valencias and lemons, which predominated. The price usually secured for Washington navels may be said to run from fifty cents to one dollar, or possibly a little more than one dollar, per box. For instance, the Duarte-Monrovia Exchange secured for its shippers an average the year through of 68.2 cents per box for all navels shipped. The San Antonio Fruit Exchange secured in the neighborhood of 85 cents per box for all navels shipped. The Upland Citrus Association, of which Chas. D. Adams is manager, has sent out the neatest and most complete report we have seen. It gives almost every feature of the business so that every grower may thoroughly understand the financial returns and the seasons or pools, rather, in which the biggest prices were secured. For this association navels constituted eighty-eight per cent of all the shipments and Valencias only three and a half per cent. For navels, they secured $1.17½ per hundred pounds which would be slightly over 82 cents per box, which is somewhat more than last year's return for the same fruit.

This association made eleven pools which is more than most associations make. The pools began with the autumn Valencia pool, September 1st, which was practically the cleanup of the Valencias, followed by the special November pool, at which the navels began to be forwarded, the regular November pool, the first December pool, the second December pool, mid-season pool, from December 20th to March 24th, and the monthly pools from then on to the end of the season. This year they have arranged for the monthly pool to begin with the first of January which, with the special pools before then, makes fifteen pools, This gives every grower the opportunity of shipping at any season of the year he may see fit.

From this it will be seen that the returns of sixty and eighty cents, as the case may be, per box, the season through, do not always indicate what each individual grower receives. In fact it surely does not, for that covers all grades. The grower of the better fruit, also the grower who has fortunately chosen the more favorable pool wherein highest prices are secured, shows better returns.

At the time we visited Mr. Van Luven, manager of the San Bernardino County Exchange, he was unable to give exact returns, but the fact that his territory has largely increased its allegiance to the Exchange for the coming year indicates a very favorable condition of returns from the growers' standpoint. In the past, the field of the San Bernardino County Exchange has been the weakest in the Exchange holdings of any section of California, for within that district are shipped nearly seven thousand cars and of that the Exchange has held little more than fifteen hundred. The number of associations connected with the Exchange for the coming year will be seven; one at Redlands, one at East Highlands, one at Highland, at Rialto, Colton, Brynmawr, and one at Redlands Junction. In Redlands alone the output has been between thirty-six and thirty-seven hundred carloads. There the Exchange association has only about five hundred cars. There is one good point to be noted with the Redlands growers. They have joined themselves into independent co-operative associations, at least, to a large extent, so that co-operation is winning its way even there. One grower in Redlands told us his returns for his entire orchard, including culls, was $1.24 per hundred pounds and the manager of one of the co-operative associations estimated that the average for the entire section would not be far from $1.15.

At Riverside it was yet too early to secure any definite figures. The Citrus Union people who were appealed to, the independent shippers and the Exchange all had no figures or even estimates to give. Riverside produces something in excess of six thousand carloads of fruit, of which about thirty-five hundred are in the Exchange. In the height of the season, three trainloads per day are regularly sent out.

In Orange county is more general following of the plan of the association picking gang. This has been found very satisfactory and more uniform fruit and greater freedom from injury from picking is thus secured. One independent shipper in that county informed the writer that he had secured from $.75 to $1 a box for all his patrons for their navels but this was disputed by some growers who said they had reason to know.

As to next year, a most hopeful feeling prevails. The crop will be large, probably about the same as last year, but the experience of the past will no doubt aid in securing wider distribution and more satisfactory prices.

CITRUS FRUITS

By C. A. Day. Pasadena

OUT-LOOK FOR ORANGES FOR THE COMING SEASON.

As to the prospective yield of oranges for the coming year, there is no reliable data at hand. The light crop of Valencias the past year, will undoubtedly be followed by a full crop. as this variety of oranges is inclined to bear in alternate years a full crop, fol lowed by a light crop, and this limited observation of the writer verifies this supposed fact in the set of this years crop.

One of the secrets of successful fruit growing is the ability to grow a fair if not a full crop in the off year, as the prices in the off year are usually much higher than with a full crop. An instance of this kind has come to my notice in the sales of Valencias for this season. A single acre of Valencia oranges, 107 trees, under the best of culture gave returns to the owner of the trees of $1148.

The probable yield of navel oranges for this coming season is expected to exceed that of last year, although many orchards coming under my observation have a lighter crop set than last year.

This, however, in a majority of cases is due to fault in culture or a heavy stock of black scale present on the trees dating back to last summer. The crop of apples on the Atlantic seaboard is reported 50 per cent. of an average crop. This was to be expected as last year's crop of apples was a very large one.

The Cape Cod crop of cranberries is reported to be light. The crop of Florida oranges is estimated as one third less than last year, with the prospects of an early movement, probably the result of last year's experience with the late frosts.

Another thing that must be taken into account is that the warm winters in California for the past few years may be followed by a cold winter this year with probable losses of fruit from hard frosts.

The liberal rain fall of last winter with climatic conditions favorable for the production of a better class of fruit with better carrying qualities and less puffed fruit in certain localities, are conditions favorable to the grower. All things taken into account, the outlook as to yield, quality and prices is by no means gloomy.

* * *

Returns from late varieties of oranges for the season just past—All late varieties of oranges, including seedlings, St. Michaels, Sweets, Joppas, blood oranges and valencias have brought good prices.

This calls to mind a paper by C. C. Chapman read before a farmers' institute some years ago, in which he said, in substance, that he did not believe in staking all on a single variety of oranges and that he had planted a number of varieties of oranges, including the late varieties. The reported sales of Mr. Chapman's late varieties of oranges the past season, verifies the wisdom of this orange grower; not to put all our eggs in one basket.

The great majority of the orange growers of California have planted exclusively the navel orange, because of its fine quality and it being a standard variety. There is a large acreage of navel oranges planted in California, and the constantly increasing yield of new orchards coming into bearing and of the growing trees in connection with lower prices have raised fears in the minds of many growers as to the future profits from this variety of orange. There are, however, some favorable conditions affecting the navel orange. California growers have no competition from navel oranges grown outside of the State, and from midwinter until the first of June it has little or no competition from other varieties of oranges and during the greater part of this period there is but little competition from other fruits. Another thing, the demand for the navel orange is constantly increasing both in the home and foreign markets. The planting of new orchards has very nearly ceased and the present high prices of lemons has stopped the budding over of lemon trees to navels. The high prices of Valencias have induced many to bud over navel trees to Valencias. Some of our older navel orchards are not yielding as large crops as formerly. The lower prices for navels have caused owners of orchards which produce inferior quality of fruit, to neglect the trees. In the rural section and near the large towns and cities, where the demand for residence property is increasing, many orchards are being subdivided for residence purposes. Everything considered, the future of first-class navel oranges is by no means discouraging.

* * *

We seem to have but little to fear from outside competition in the increased production of Florida oranges. The possible increase of production of oranges in Cuba may have some effect on the prices of holiday and of early winter oranges, but the supply of oranges from Cuba will not be navels and the time of shipment of Cuban oranges will last from early August to January, possibly February, not coming in competition after midwinter. We are told that the oranges grown in the tropical climate of Cuba will not hold on the trees very long after coming to full maturity, and have not the keeping qualities of the oranges grown in the sub-tropical climate of California. It is probable that the early oranges from Cuba will come in competition with the Valencias in the fall.

The present high prices for Valencia oranges cannot be expected to continue. The Valencia orange is of good quality and a good keeper, but there has of late been a large increase in the acreage of this orange in Southern California. The high prices of other late varieties of oranges which during a part of the season come in competition with the Valencia, will undoubtedly stimulate an increased planting of these varieties, and possibly the Cuban oranges in the near future will also come in competition with the Valencias in the fall market. Another thing must not be forgotten. Our late varieties of oranges which supply the summer markets of the East, are marketed at the time when there is a large supply of summer fruits. I am not presenting the adverse side in order to discourage the growers of Valencia oranges, but to give a timely caution. not to overdo a good thing. I believe the Valencia orange and other late varieties have a good future provided an excessive increase of late varieties does not bring about an over-production and a glut in the summer market with consequent low prices. Success in the growing and marketing of oranges, or other varieties of fruits, depends upon the foresight that carefully considers the future supply and demand, with the competing factors of oranges produced in other sections, and the competition of other fruits in the market.

We have an instance of this in the case of an orange grower of Sierra Madre, who some years ago planted out an orchard of the Japanese orange, the Oonshu. With the nearby home markets of the cities of Pasadena and Los Angeles he sold this variety of orange at good prices, because its time of ripening came when there were no other varieties of oranges coming in competition. Last fall a considerable shipment of the Oonshu oranges arrived in San Francisco from Japan. The prices in our home market for this orange, evidently guaranteeing fair returns for the long shipment to an orange-producing section, as a part of this shipment was put on the markets of Los Angeles and Pasadena.

LESS CLIPPER-CUT FRUIT.

It will be recalled that the principal lesson which G. Harold Powell, an expert from the Department of Agriculture, Washington, D. C., sought to instill into the minds of the orange pickers of California as the result of his months of investigation in orange decay, was that, of all the causes of decay of fruit in transit, none were equal to that of the carelessness of the pickers. Mr. Powell went into citrus orchards in all parts of Southern California, in some of which there was the utmost carelessness, and in others greater care in the fruit picking. In no case, however, did he find freedom from clipper-cut fruit. Amongst the most careless, it was common to find forty to sixty per cent of the fruit seriously injured. The more careful pickers showed fifteen per cent and possibly on down to ten and twelve per cent. When these facts were brought to their attention, more rigid rules were laid down for the guidance of the workmen and in some orchards the injured fruit was reduced to three and four and five per cent, but this at a material increase in cost of picking.

Owners of the orchards have laid this loss largely to the carelessness of pickers, and often justly, of course, but the pickers in turn have made the counter claims that the tools with which they had to do the stem cutting were such that it was impossible to do ordinarily expeditious work without injuring the fruit. There are, perhaps, a dozen kinds of clippers, some with the kind working in a sheath, others with the ordinary scissors cut, others with the sharp edges cutting against the blunt ones, but all with the steel points endangering the delicate texture of the orange.

To overcome this injury, the growers, many of them, have largely increased the cost of gathering the fruit by insisting upon more careful work, and, as far as possible, no injury to the fruit. With this, comes the necessity for closer cut stems, so that there will be no later injury to the fruit from the long cut stems puncturing other fruit in the same box.

These facts have all caused the seeking for the tool which would accomplish this work with the greatest degree of rapidity and the least possible danger of injury. By far the best of these which we have seen is one patented by Mr. E. F. Steffa, of Pomona, and it is so simple, practical, and with the possibility of being cheaply manufactured that we believe it will be the coming clipper.

The clipper is simply the ordinary curved scissor cutter, excepting that one of the blades is practically a double blade working over these two. This gives a device with a forked blade, between the forks of which the stem of the orange is placed, when, with slight pressure, the other blade closes in the opening, severing the stem with a square cut. This point we believe to be a strong one, for with the ordinary clipper the stem may be cut at any angle, leaving the sharp pointed end to greatly injure the fruit lying next to it. The forked, or, we may say, stationary blade, is rounded and blunted in such a way that only by the grossest carelessness can fruit be injured. The cutting blade with the sharp edge and point is considerably shorter than the forked blade, and thus at all times and in all positions it is so guarded that it is impossible to touch the skin of the orange with it.

The blades of the clipper have a decided curve upward, which makes it possible to clip the stem closely, and still further prevents the possibility of jabbing the fruit with the ends of the clipper.

It is hard to give a word picture which will give an accurate understanding of the advantages of the clipper in actual work. We know, however, that statements of its effectiveness by practical orchardists who have given the clipper a severe test, prove that it has merit which makes it worthy of investigation by the careful archardist. In addition to these, managers of various packing houses have made close observation from the viewpoint of packing house managers and assert that it will, when in general use, prove a great safeguard against clipper-cut fruit. In fact, it may be said that it will practically make clipper-cut fruit an impossibility.

If this tool can be brought into general use it will, we believe, mean much to individual growers and much to California in financial returns and in reputation for sounder citrus fruits. We hope to be able to give an illustration of this valuable little tool in the next issue of the Cultivator.

"THE COUNTRY BEAUTIFUL."

In many of the smaller cities of this State efforts are now being made to beautify them. The movements for the abolition of the billboard and hand bill nulsance, the cutting of the weeds and grass about public and private places, are all in the right direction. Well kept lawns, clean streets and alleys, vacant lots well delivered of weeds are all part of the work of making a city clean and beautiful. These things help any town. They attract residents and draw capitalists. But while these efforts are being made by residents of our towns why should not the residents of the country districts also make reforms along this line! Anyone passing through some sections of the county is struck by the ill-kept farmhouses, the surroundings in many instances being anything but beautiful. The fields show an abundant harvest, sheep and cattle are grazing over the pastures, and there is everything to indicate that the farmer there is prosperous.

But about the house and scattered over the farm are evidences of neglect in making the premises attractive. The lawn is ill kept, the steps worn out, while about the fences, weeds have grown up as to almost obscure the view. Over the farm there are trees in sad need of trimming, and the whole farm indicating that no effort is given toward making it look beautiful. Beauty will add to the value of any farm, and those who would make the country more attractive and their properties worth more money should give some attention to these things. The building of good roads will do more than any other one thing to bring about improved conditions in our country districts and it is already in evidence. We should have beautiful country districts along smooth and well improved highways, as well as beautiful trees, towns and cities. They are all important in the life of our people.

* * *

OXALIS.

Many bulbous oxalis are well worth cultivating on account of their handsome flowers and foliage. The principal danger to be guarded against in growing oxalis is putting bulbs in too thickly, thus crowding the soil with too many roots and starving the plants. Grown in this way they may produce few flowers, which last but a brief period.

O. hirata rosacea is a good plant, keeping rather close to the soil. The flowers are on single stems, three or four inches long, and do not droop like those of some of the other species. The bulbous oxalis close their flowers during the night and during dull weather. This species in addition to its upright habit is attractive even when closed, as the color of the buds contrasts well with the greyish green leaves.

Oxalis cernua is the Bermuda buttercup. With rather light, rich soil, a single bulb will give a surprising number of flowers. In this species they last only a few weeks, being of a fragile nature.

O. rubricaulis is grown principally on account of the stems and branches being of a brilliant red color. The flowers are pale rose and not many of them to a plant. Being a procumbent habit, it is suitable for hanging baskets. The best species of all for this purpose is the old O. versicolor. Some bulbs started in small pots and transferred to baskets, make beautiful objects for hanging in a cool observatory. They flower during midwinter. O. Bowiei is the largest leaved species of the genus and one of the easiest to grow. It has large rose-colored flowers on long stems. They should be started into growth the end of September.

The dwarf form of O. lactiflora is one of our best window-flowering plants if given an abundance of light and plenty root room. O. multiflora and O. malba are well known for this purpose. A species under the name crydentelles is well suited for basket work. For late flowering in the open border the bulbs should be planted out not later than the end of August. Bowiei, O. hirta rosacea and O. crydentelles all do well under those conditions.

* * *

TALL GROWING NASTURTIUMS.

For quick effect before permanent climbers are available, as in covering the foundation walls of a house or the lattices beneath piazzas, the tall growing varieties of nastrutiums prove exceedingly satisfactory. They afford the handsomest of color effects with their brilliant bloom and clean, attractive foliage, and few things are easier to grow or less particular as to soil.

* * *

PROTECT THE TREE.

The ruthless destruction of trees along country highways is evidently largely the result of ignorance, with all its lack of appreciation of either beauty or usefulness. In many rural districts throughout the country, the landscape is fairly denuded of tree life, simply because the abutting owners cannot realize that every good tree is worth the ground it occupies many times, and is more valuable as a feature of the landscape than as firewood. Unfortunately the country school house does not yet ground its pupils in the primer of natural economics, so that the tree that draws its modicum of nourishment from the boundaries of the grain field or truck patch, even from the other side of the fence or hedge, is dubbed an enemy, to be destroyed at a convenient time. In the present condition of knowledge of the higher conditions of life, the tree is too often condemned as a nuisance, which on the contrary should attract the veneration and care of the community. It has become the duty of public instructors to incorporate into the school curriculum under their charge a liberal proportion of nature study, that the pupils may learn to act with understanding and discrimination when the question of trees and their care becomes a personal one. Let laws be enacted in every State that will at least provide a sensible method of control and management of trees, along our country highways.

* * *

RURAL IMPROVEMENT.

The campaign for rural landscape improvement is being waged with considerable vigor in many sections of the country. In many States, in order to reach country districts, legislation has been enacted in several lines of improvement, and it is very much to be desired that the way should be cleared at the earliest possible time so that the experiences and examples now rapidly maturing may be as rapidly taken advantage of. With public interest so widely apparent, we may confidently expect an era of outdoor improvement as characteristic of our moral force an denergy as our commercial prosperity has exemplified our material progress.

* * *

FOR VILLAGE AND HAMLET.

"If your store front, residence or fence is dingy, order it painted.

"If your awning is old, torn or faded, get a new one.

"If your sidewalk, gate or fence needs repairing, fix it.

"If your advertising sign is old or faded, take it down or paint it.

"Resolve never to throw paper in the streets.

"Destroy the young weeds that are starting on your property and on your neighbor's property.

"Burn all the rubbish possible—allow no one to throw it on streets, alleys or vacant lots.

"Promise not to spit on the sidewalk.

"Organize a block improvement society, and allow no weeds to grow on sidewalk area or vacant property in your block.

"Ask your milkmen, grocerymen and expressmen to have their wagons painted.

"Irrespective of the size of your house make your lawn the finest.

CREATE TASTE IN CHILDREN.

What we want to do is to teach the children taste; get taste into the child; get taste into the household and then finally taste into the community, and when we have done this we need not fear the results. The lack of taste in the community generally is an unfortunate fact, notwithstanding our grand school system, and may be attributed, in large degree, to the failure to appreciate its necessity by our educators. Reform in many branches of public improvement would be far easier of accomplishment now had the children of the previous generation been trained in the fundamental principles of taste, the power of perceiving, appreciating and discovering beauty and excellence. The more we consider the curriculum of our public schools, the more we perceive how it could be improved to meet the changing conditions of our American life. Our children need far more than the three R's to fit them for citizenship as it is dawning upon us. The atmosphere and appurtenances of the school room should tend to impart culture and taste, which in turn is transferred to the home, and thus ministers to the general upbuilding.

The sweet peas should be well watered in the evening and heavily mulched with litter.

It is a good plan to go over the annuals and cut away a good many of the old branches. This will cause the production of new branches and these, if the soil is kept rich, will give flowers quite as large and fine as those which appeared earlier in the season.

The cineraria is one of the prettiest of the winter blooming plants. The flowers are produced in great numbers, in large flat clusters which nearly cover the plant, being very rich and varied in coloring.

To increase the quantity and quality of blooms, asters should have frequent hoeing and fertilizing. Pick the flowers freely as they appear, and the plants will continue to bloom until frost.

General Agricultural Notes

FERILIZING GRAPES.

The widespread idea that California soils are well supplied with potash had doubtless more or less influence in limiting the use of this valuable plant food to a considerably greater extent than the facts really warrant. Particularly is this the case in the northern part of the State, and with such crops as draw heavily upon this element. The uplands generally, and especially on those on which have been grown fruits and grapes for a number of years in the northern counties are far from abundantly supplied with available potash as numerous published analysis have shown. The same fact is more generally recognized by those who have not observed the results secured by the use of properly supplied fertilizers. On soils in the regions indicated profitable fertilization should always include some form of potash, for fruits, grapes and market garden crops.

One of the crops which is likely to show the best results from the use of potash, especially if used in connection with nitrogen and phosphoric acid, is the grape.

As a basis for discussion of the relation of potash to the grape, the report of the California Experiment Station for 1894-5, gives the following as the amounts of the several ingredients removed from the soil by an average crop of grapes:

	Potash	Lime	Phos. Ac'd	Nitrogen
Crop of 10,000 lbs	50.00	10.00	15 2	17.0
Seeds, 646 lbs	1.48		5.7	
Flesh, 9,154 lbs	47.44		8 9	
Wood, 2,010 lbs	15.69	21.6	8.7	

The above shows the grape to be a gross feeder, especially on the side of potash. As compared with citrus fruits it may be said that the grape removes at least a fourth more potash, a half more phosphoric acid, and only about one-half as much nitrogen. There is no way in which the mineral fertilizers, potash and phosphoric acid, can be returned except by direct fertilization. Of the nitrogen it may be said, however, that much saving may be made by growing leguminous crops between the rows and turning them under. The extensive use of stable manure on the grape is not looked upon with favor, as it is said to induce fungous attacks by weakening the vitality of the plant.

A favorable proportion for these ingredients, nitrogen, phosphoric acid and potash, is 2, 8 and 10 respectively. Such a fertilizer may come from nitrate of soda, 100 lbs., dissolved bone 400 lbs., potash, 180 lbs. The potash may be obtained either from the sulfate or the muriate of potash. In California the sulfate is easier to obtain, as it is in common use for fertilizers for citrus fruits. For the grape, however, the somewhat cheaper muriate is as acceptable as the sulfate and carries practically the same amount of available potash. In both of these forms of potash the entire amount of available potash is perfectly soluble, and therefore immediately available for the use of the plant.

The rational application of fertilizers is daily becoming better understood on the Pacific Coast, and there is an increasing interest in the matter. The question as to whether or not it is best to use fertilizers is one that cannot always be determined from a soil analysis, but it is rather a practical commercial one, viz: can we produce enough more to pay for the added cost of the plant food and labor, leaving a surplus for profit. If we can determine this to be the case by experiment, then it matters not what may be the soil composition, it will pay to use the fertilizer to force the growth and crop within the limits of safety to the health of the plant.

In all such work the grower must give particular attention to the physical condition of his soil, for no beneficial results can be expected until the physical conditions are such as to allow the added plant food to have the proper relation to moisture and atmosphere.

There is quite a difference in the practice in purchasing fertilizers in the northern and the southern parts of the State. In the former it is common to order the several simples to be mixed after the idea of the purchaser, which practice is one to be encouraged as ultimately leading to a much more rational use of plant food than where implicit confidence is placed in the fertilizer manufacturer. In the south by far the larger part of the trade depends upon certain brands of complete fertilizers. While generally more certain results can be depended upon from the use of complete fertilizers, those carrying all three of the plant food elements, yet there are doubtless numerous instances where at least one of the ingredients could be cut out and the results obtained not be impaired. Such a knowledge must be carefully worked out, however, by careful trial upon the soil and crop, taking as a basis the draught made by the crop and inquiring of the soil the effect of lessening any one of the ingredients named.

ABSORBENT PAPER TO SAVE PEACHES.

From an eastern exchange we get information of a method of lining cars with absorbent paper, which prevents deposit of moisture on fruit, thus preventing decay:

Strips of absorbent paper are placed along the side and ceilings of cars which are loaded in such manner that the air within the cars has perfect freedom of circulation between the contents of the car and the sides and ceilings. The moisture, that condenses as the ice melts, is taken up by the paper more rapidly than the fruit will absorb it. This has the effect of lessening the falling away of the fruit and causes it to hold up much longer and to reach destination in much better shape. The process and its application is limited to refrigerator cars.

HOW TO GAIT SADDLE HORSES.

An expert trainer of saddle horses has given us the following practical directions for teaching a horse the saddle gaits. Always select the gait you wish to go and make the horse take it; don't allow the horse to decide. Always go into the other gaits from the flat-foot walk. Never let your horse rush away when first mounted, but instead start in a walk. Do not keep him constantly at one gait, but change quite often, otherwise he will soon become adapted to the one gait in which you ride, and practically lose the other gaits.

For a trot slacken the reins a trifle, and steadily take hold of the mane or touch the neck with the right hand, and at the same time rise slightly in the saddle, urging on the horse gently. If he makes a mistake, and mixes, pull him back to walk at once, and repeat the maneuver. For the canter, slacken the reins, incline your body forward, raise your right hand as if to salute, and cluck to the horse. When he starts, take sufficient hold of the reins to pull in his nose and make him arch his neck.

Many highly trained horses will go into the canter at the mere inclination of the body. For the rack, or single foot, tighten the reins and give the bit a number of almost imperceptible jerks, at the same time urge him on with voice or whip, as he requires. If you feel him falter, or as if he was going to change into another gait, slightly shake the bit and urge him on. It is well to remember that this last gait is the hardest of all on the horse; for this reason he should not ordinarily be asked to go at this gait for more than a mile without change.

THE VALUE OF CLIPPING QUEENS.

As our bees are situated amid low shrubbery, where the clustering of a swarm in some inaccessible place would be unlikely to happen, we did not deem it necessary to clip our queens the past spring. The result has been that many of our finest swarms have gone to the woods after being hived, in several instances taking with them valuable queens. In all, I have lost somewhere near $50, as a result of our queens being able to fly. It would have taken one man about half a day to have clipped all the queens in this yard.

At the clipping season there are but a few bees to the hive and the most inexperienced can readily hunt out and clip a queen. It is, in fact, about the easiest work the beekeeper will have. Hereafter all the queens in my yards will be clipped each spring, or as soon as they are mated.—O. J. Farmer.

Changing Seed Wheat—The Stockton Mail in an article on the above topic, makes some well-taken suggestions as to the practice of sowing the same seed repeatedly in the same locality—a custom which many of our older farmers have followed for years. What the Mail says as to wheat seed is true as to sowing barley and oats. It is a mistake to crop a given piece of land a series of years without both change of seed and rotation of crops. Back in the Eastern States we never think of anything but rotating crops every third or fourth year, unless it be very rich bottom which will stand corn for a series of years. But out in this country our farmers have no hard and fast rule about seed change or crop rotation. If we are to get the best results from our lands—the biggest yield—we must give nature some of her ways of recuperating her waste energies.

This is what the Stockton Mail says on the subject:

"The seed wheat quest is probably the most absorbing matter farmers, millers and grain dealers have had to deal with. Various theories have been offered as to the cause of the deterioration of the cereal, but so far no plan has been suggested that has been followed to any extent. There is one fact that buyers say is certain, and that is that California wheat is far inferior to that of other States. Oregon and Washington are producing grain that is of much better quality than that grown in this State. It is not because the local soil is worn out, as the richness of California soil is proverbial. The real cause as given by those who have made a close study is that the seed used is not up to the standard.

A mistake that has recently been called to the farmers' attention is that of sowing the same seed repeatedly in the same locality. To sow seed from places where the climatic conditions and the soil are different has proved most beneficial. It is now becoming the custom to plant West Side wheat on the islands or in other parts of the country, while island seed is given the same treatment on the West Side. The change of soil and the slight difference in the climate has produced a very desirable effect. The wheat is stronger and the yield is much better.

Suggestions are being made every month by scientists who are working on the question. The farmers of the present time are following these suggestions and are securing better results. The day of regular routine farming is no more. The up-to-date farmer is progressive and is much more of a student than his father was. Much good has been acquired from the State farm at Modesto, and many things of interest have been brought to the farmers' attention.

Many farmers favor the introduction of the Oregon wheat and are going to plant it next season. The Oregon blue stem wheat contains a large percentage of gluten and is a hardy cereal. It yields abundantly and is exceedingly clean. A sample sack of the wheat which Melone & Perry recently received speaks well for the cereal. Taken from the harvest field it looks as clean as California wheat does after it has been put through a cleaning process. In fact the farmers of Oregon experience no trouble with rust and rank growth. Their wheat is very clean. The blue stem ranks with the Australian variety for milling purposes and is similar to it. Those who have tried the Kansas wheat prefer the Oregon variety. Of course, the Kansas seed contains a larger quantity of gluten, but the color is not as acceptable as the Australian or Oregon. The cereal is red and is slightly smaller than the blue stem.

* * *

What Rockefeller Said—Last week we published in these columns, a purported statement from John D. Rockefeller, in which it was said he predicted hard times for this country in or about 1907. Naturally this statement has the tendency to disturb the public mind and has called from Mr. Rockefeller an explanation of what he did say: This seems to be the simple story.

Talking with a friend a few weeks ago he advised him to "hold on to his money; he might need it in a year or two." The remark was purely personal and meant simply that in the particular matter that person was engaged in he would be able to use his money by keeping it on hand for an opportunity certain to arise than if he invested it now in anything outside. This advice lost nothing when it passed beyond the person for whom it was intended and was soon perverted into a general warning for everybody to trim sail. It is well to have the perversion promptly corrected.

There are no clouds on the commercial horizon. The well advertised weaknesses and abuses among the big insurance companies of New York afford a pretty good test of credit and confidence. In shaky or uncertain times such revelations would be almost certain to usher in a panic. Such would have been the case if conditions were like those of 1873 when excessive railroad building had strained the credit system to the breaking point and the failure of Jay Cooke & Co. was simply the last straw. So in 1893 failures and troubles fell upon a soil fruitful of panic. The continued coinage of silver threatened a dislocation of the standard of value and under such circumstances the bad times harvest was white for the reapers. Little time was lost between the first alarm and the breaking of the storm.

Conditions are radically different now. Credit is not overstrained. Even the great insurance revelations do not affect it. The money standard is beyond assault. Buttressing all this is the tremendous fact that the United States is passing from among the debtor nations of the world to the creditor class. Dangers which have menaced this country heretofore must now become fewer and far less potent for evil. The general situation is radically different from 1873 or 1893.

Like the poor we have always with us one danger—tariff smashing. Every tariff revision ever made in this country in a downward direction and against the principle of protection has produced a panic. As the great business and labor interests of the country see this fact standing out in ominous distinctness they are throwing their power against such useless and dangerous agitation and uncertainty.

It does not follow, says the Des Moines Capital, because Rockefeller has amassed the biggest fortune in the world by Standard Oil methods that he is an exceptionally good judge of general conditions, but his business extends throughout the civilized world and he is in touch with conditions that could hardly fail to give him early premonitions of any rising commercial storms. That is what made the first report of his alleged fears so disquieting, just as it now gives solid satisfaction in the correction and contradiction.

* * *

Common Sense Spraying.—A writer in the N. W. Horticulturist makes the point that "much of the spraying done on trees gives no results, because it is not done with any degree of intelligence. The sprayer simply goes over his trees, in a perfunctory sort of way, not knowing how to do his work nor caring, in some cases, whether the work is well done or not." This is certainly true. We know it because complaints come to the Cultivator of spraying done in orchards which is vastly injurious, in some cases blighting the fruit and burning the foliage until it drops off. We have an example of this careless work of the sprayer before us now. One side of the fruit is blighted, while the foliage is yellow, showing that the compound used was too strong. There was no intelligence exhibited by the sprayer, either in mixing his material, nor in the method of its application. Thoroughness is necessary, vitally necessary, but carelessness is criminal.

An operation can always be more intelligently performed if the reasons for doing it are thoroughly understood. This is emphatically true of spraying. If the operator does not know what he is spraying for and why he is doing it, it is merely an accident if his efforts avail anything. It is not necessary that he know the name of every disease or the complete life history of every insect, but it is essential for him to know their vulnerable points and the treatment that will reach them.

To spray an orchard simply with no idea of what is needed to clean it, is a dangerous proposition. Before going to work on an orchard, to clean it of fungous diseases, or if insect pests, some well informed horticulturist ought to inspect it to ascertain what is necessary to get the best results. It requires experience and knowledge to know these points and to meet them as the exigency of the case requires.

Spraying for fungous diseases is largely a preventative measure, not a curative one; hence their coming must be anticipated. This likewise applies to some of the insect pests. Spraying should therefore be looked upon as an insurance of the crop. Such efforts will not give the same proportionate returns every year, but the appearance of destructive disease and insects of some kind may be expected every season and it is not often that they fail to come, so that efforts put forth in anticipation are seldom lost.

We recall hearing Frederick Maskew, the apple growers' authority in the southern part of the State, say, "the effect of spraying is, in a measure, cumulative." That is, he meant, we suppose, the benefits are not all manifest during the season that the application is made. Especially is this true of plants which form their fruit buds the previous season, which is the case with many of the fruits. An apple tree, for instance, which is seriously attacked by insects or loses its foliage from disease, is not likely to properly mature its fruit buds for the next season's crop, whereas a tree that is perfectly healthy will, under normal conditions, perfect its fruit buds for the succeeding season.

Thoroughness is an absolute essential. Negligence in this direction is the cause of a large proportion of the failures to obtain good results from spraying.

* * *

The Good Roads Problem—The time when work can be done to advantage on the public highways is about over for a while. The heavy rains of last winter left many of the cross roads, and indeed, the main roads, in very bad condition and this summer, for some reason they have not been repaired to the extent they should have been.

Who is to blame for this neglect? We certainly expend money enough in California to have a good road system. What is done with it? The Boards of Supervisors throughout the State have the road fund in their keeping, they make the contracts for road repairing and the people look to them for results.

Before this time every main road in this, and, in fact, all the counties of the State should have been leveled up and oiled, sanded and oiled a second time, so that when the rains come this winter, they may be made hard and useful for next year. Some months ago the Cultivator called attention to the system of cheap and excellent road making in vogue in the State of Missouri. It consists of a drag (without teeth) of sufficient weight to level off the road; used before a rain it puts the highway in order and after a rain it fills the uneven places and makes an excellent, durable summer road.

This, or some other device could be used to advantage on the roads in the county districts while the Supervisors are waiting for money to oil them.

We certainly spend too much money for roads which we do not get. There ought to be a general upheaval of the people in the interest of better roads. If we are to fill the country with desirable people we must give them highways to and from the towns in their locality.

Goods roads to market are imperative. The farmer will locate where these are at command.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

The Redlands Orange Producers Co. will erect a packing house seventy by one hundred and forty-four feet, at a cost of $8000.

The grape crop was somewhat damaged at Grass Valley last Friday by a very heavy frost, accompanied by a slight snowfall.

The State horticultural officials are figuring on the erection of a new building in the Capitol grounds to be used as an insect house for the culture of parasites beneficial to fruit.

B. G. Johnson, superintendent of the date farm at Mecca, will leave shortly for the Persian gulf to secure cuttings of the date palm for propagation at the date farm.

The date trees at Hanlon's Heading, in the Imperial country are now being picked of their annual crop of dates. They are of an unknown variety, but of excellent quality.

Some of the grapes in Sonoma county are showing very heavy per cent of sugar, going as high as twenty-three per cent. Zinfandels are bringing $20 with the premium on Petit Bouchet.

The walnut crop in the El Monte section is to be greater this year than ever before and with the price of thirteen cents per pound for the best nuts the section will have a very prosperous season.

Very heavy shipments of grapes are now being made daily from Folsom. Reports of the sales in the east are to the effect that grapes are bringing good prices which is stimulating shipment and making the growers prosperous.

Sixty tons of apples is the product of the Alexander Lamenton orchard, which is 6000 feet above sea level. The entire crop will be sold in Redlands this year, and it will amount to a goodly store of cash.—Redlands Citrograph.

An innovation this year at the Santa Anita Ranch east of Los Angeles is the canning of grapes for the market. The packing house at Arcadia has been utilized for the cannery and is turning out large amounts. This ranch has seven hundred acres devoted to grapes and the crop is excellent this year.

The Rialto Citrus Union held a meeting Saturday and elected officers for the coming year. The Union, with the Hand Fruit Co. of Riverside, jointly own the packing house formerly occupied by the Fruit Exchange and will proceed at once to double the size of their house and equip it with the latest improved machinery.

The Highland Fruit Growers' Association, at a meeting held last week, gave the contract for packing and shipping to the California Citrus Union. This association controls something like one hundred and twenty-five cars of citrus fruits and the Messenger of that place states that the Union will this year put out close to two hundred and fifty cars.

The deciduous fruit growers in Tulare and Kings counties are closing up one of the most prosperous seasons they have ever had. The reports from the Earl Fruit Co of fruits shipped from that district showed that an average of $1400 to $1500 per car was obtained for peaches which was between $400 and $500 above the average price. These prices mean that the growers receive from $40 to $50 per ton net.

The Marysville Appeal says that some of the growers are still shipping their Thompson seedless grapes, as the prices still remain fairly good, and are running the risk of drying what remains of their crop before the rains set in. There is a strong, brisk demand forming for bleached Thompson seedless raisins at from 9 1-2 to 10 cents or 8 cents and better in sweat boxes. Standard Thompson seedless are being quoted at 7 cents, choice at 8 cents, fancy at 9 cents and extra fancy at 10 cents.

A Cultivator representative writing from Watsonville says that the Pajaro valley is gathering the largest, finest crop of apples that has been had for many years. The apples are sound and good. The crop is so heavy that many trees are broken down and in some instances ruined. The shipments out of the valley have averaged about thirty cars a day since the season opened, making over six hundred cars so far this season. Regarding the stock interests, he says they are in a very flourishing condition.

AGRICULTURE.

The sugar factory at Chino has sliced over 25,000 tons of beets so far and has fully as many more to slice before the season is completed.

The hay crop in the Ukiah valley will be about fourteen hundred tons this year, which is less than last year's crop, owing to the fact that a large amount of grain was threshed.

The Lima bean harvest is in full blast with twelve threshers in operation in this valley. The county crop is estimated at 400,000 bags, which is very close to the record, and the price is expected to be good, many lots being contracted for at 3 cents.—Santa Paula Chronicle.

The second crop of melon vines planted in the Coachella valley is doing fine and full of young fruit. Prospects are that there will be a good supply of this fruit at the time of the year when they usually are very scarce. Asparagus from this valley is now in plentiful supply from the second crop.

At the annual meeting of the San Gabriel Farmers' Club at Alhambra Saturday the following officers were elected: President, Dr. F. E. Corey; vice-president, Major E. A. Routhe; secretary, H. E. Lawrence; treasurer, Mrs. A. C. Wheat. The meeting was addressed by C. A. Day, of Pasadena, on the subject of improvement of roadways.

Sixty leading canteloupe growers of the Imperial valley met near Brawley and contracted with Lyon Bros. of Chicago to handle their crop for next year. The contract contemplates the shipping of a car or two of melons weekly during the entire season. One thousand pounds of seed are to be brought in from Rocky Ford for the planting next spring. It is estimated that about one thousand acres will be planted at Brawley and that a trainload of cantaloupes will leave daily during the height of the season.

From the sales made last week, both in Oregon and California, it would look as though the hop growers are afraid of the market and that they could not hold together to secure the price which well-informed producers think they ought to have. Instead of getting twenty cents per pound, as it was thought hops would command, several sales have been made at from ten to eleven and twelve cents, which is very nearly bed rock for the grower. As the crop is short and the world's supply also short, it is thought that the market will be good for twenty cents, at least, before the first of the year.

The Dinuba Advocate is responsible for the following story: George Bence, who is engaged in farming on a portion of the old Buckman place, three miles north of Exeter, raised two hundred sacks of yellow Danver onions on a half acre of ground this season, a sample of which may be seen at the rooms of the Tulare county Board of Trade in Visalia. The sacks will average about 100 pounds each and Mr. Bence received not less than 1 1-2 cents per pound for the onions, as they have been sold at retail by the storekeepers at Exeter for 2 cents per pound, so his returns from that half acre of onions amounted to $300.

LIVE STOCK.

E. W. Crook of Lincoln is building up an extensive squab plant and hopes to find a ready market at San Francisco for all that he can produce.

The largest shipment of fresh meats ever made to the far North was sent from San Francisco last week. The shipment consisted of fifteen carloads of mutton and beef.

The fair at Hanford next week, from October 9th to 14th, promises to be one of the best ever held in that section. Poultry and live stock exhibits will undoubtedly be good and the race track promises to be fast.

About one hundred cans of milk are being shipped from the station at Buena Park to Los Angeles daily. These shipments are made owing to the fact that the condensing plant there is practically closed for repairs.

One of the interesting features to stock men at the Hanford fair, next week, will be the auction sales that will be held daily. These sales will commence just after noon each day and before the racing events of the afternoon.

The Pacific Creamery Co. at Buena Park, better known as the manufactuerers of the famous Lily Cream, is making many needed repairs to its factory and expects by the first of the year to be in a position to do bigger business than ever.

J. B. Haggin, the famous fast horse man, has announced that he will sell his fine strain of racers. It is further announced that his place, Rancho Del Paso, near Sacramento, is likely to be divided and disposed of. The ranch is supposed to be worth fully $1,000,000.

The Clarence Berry ranch, consisting of twelve hundred and seventy acres of reclaimed land of Roberts Island in the San Joaquin river has been sold to four Humboldt county dairymen; consideration, $90,000. It is announced that the purchasers will divide the tract into quarters and will make great dairy ranches of the place.

Fred Jennings, a prosperous rancher living near Lemoore discovered a can of poisoned wheat in his granary a few days ago that he had used in poisoning squirrels, and believing that nothing would kill a hog, dumped the contents into his hog pen. The result was four fat porkers turned up their toes and many others are feeling the effects of the dose.—Lemoore Republican.

MISCELLANEOUS.

The long hoped for local Weather Bureau Service began actual operations at San Jose last week.

Paso Robles has let the contract for the municipal bathhouse, to cost $14,139, which is to be completed by February 15th.

The State Board of Forestry met at the office of the governor at Sacramento Saturday and decided to offer the position of assistant forester to T. P. Lukens, of Pasadena.

The San Luis Obispo Polytechnic School has started out this year with an attendance of eighty-eight students, as against thirty last year, and more coming from all parts of the State.

A meeting of the Coachella Valley Producers' Association is to be held Saturday, October 7th, for the purpose of considering the proposition of purchasing the plant of the refrigerating company at that place.

Hatfield, the so-called rain-maker, will commence this season's operations in the San Gabriel mountains about November 1st. He proposes to produce a precipitation of eighteen inches of rain the coming season.

A seventy-three acre tract of land in Riverside county has been bought by th Santa Ana Valley Irrigation Co., and the Anaheim Water Co., for a consideration of $8000. The land is water-bearing and will considerably increase the water supply of these companies.

A great artesian well was struck at a depth of 1700 feet on the Nailor ranch, twelve miles south of Corcoran, Kings county, last week. When the vein was struck the pressure of gas and water forced a column of sand and water to a height of two hundred feet above the surface.

The annual meeting of the State grange of the Order of Patrons of Husbandry is being held at Napa this week. There is a large attendance of delegates fram granges over the State, besides a large number of visitors. The annual reports show a large increase in membership during the past year.

Citizens of San Jacinto and Hemet and surrounding territory have asked Senator Flint to use his influence to secure an oppropriation of $3,000,000 from the U. S. Reclamation Service to build a dam in the San Jacinto canyon, Riverside county, which would irrigate about fifty thousand acres. The plan proposes the absorption of the San Jacinto and Hemet water systems and the merging of all irrigation interests in the region for a radius of twenty miles.

Rich Lands in Kings and Tulare Counties

A District of Magnificent Possibilities for the Agriculturist, Horticulturist and Stockman. The Most Fertile and Productive Section of Central California, where Sixty Varieties of Products are Annually Produced and Sent in Carload Lots to the Markets of the World. By J. J. Steadman.

Some weeks since the editor of this paper made a tour of inspection of the region, now so much talked and written about, and known to the public as the Kings and Tulare Lake district, situated in the heart of the San Joaquin valley, on the main line of the Atchison, Topeka and Santa Fe Railroad.

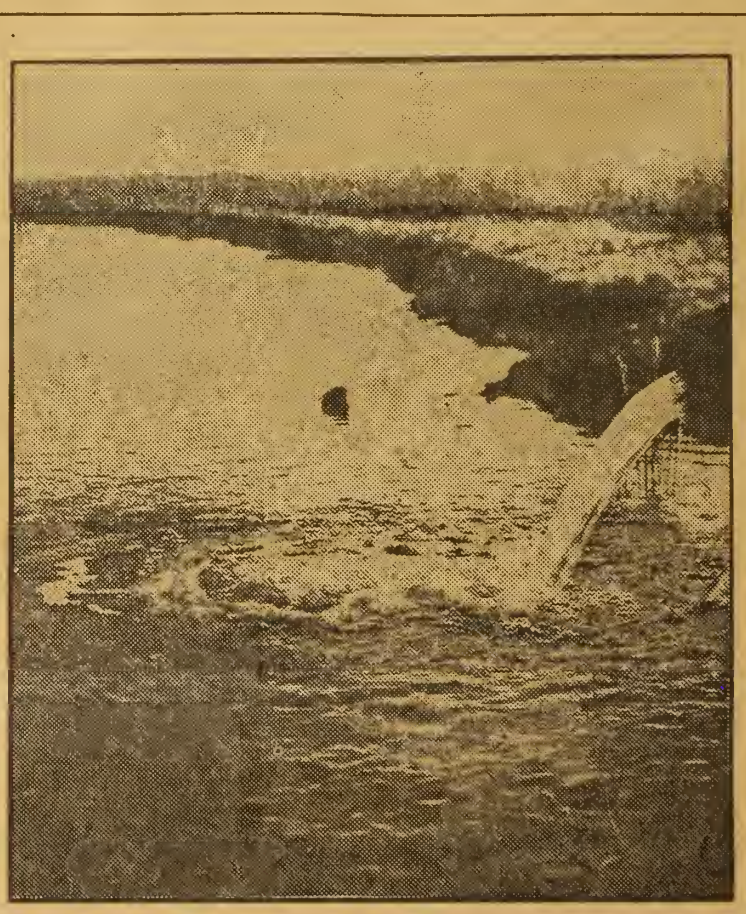
Much has been written of the marvelous possibilities of this country, within the past twelve months, but to comprehend its development, what is being done there today by the men of brains, energy and wealth who are "creating a new empire," under the most favored conditions which could fall to the lot of tireless pioneers, so to speak, one must, for himself, ride the region over, and with pencil and book note the wondrous strides of progress being made by the army of people today employed in transforming a vast region of 750 square miles of virgin soil into a veritable farmers' paradise.

Let me remark in passing, that among the hundred or more leaders of this mighty army of agricultural workers, H. J. Whitley of Hollywood, known far and wide as the "wizard" promoter of this decade, is at the forefront. It was he who, about a year ago, went over this country, examined its condition, took note of the wondrous richness of its soil, its equitable climate, the exhaustless source of its water supply, its proximity to the markets of San Francisco and Los Angeles, and determined that here should be founded a model town, the appointments of which shall rival the most beautiful city in the commonwealth of California. To his aid he summoned a coterie of experienced town builders and country developers who have been associated with him at Hollywood and elsewhere for years, and organized under the name of the Security Land and Loan Company, purchased as a nucleus for their operations and adjacent to the S. P. R. R. about twenty-five miles along the Santa Fe of the Tulare Lake lands, and upon these lands are working a transformation which may best be understood by a visit of inspection.

* * *

Climate.—To begin with, this region, located at the base of the Sierra range of mountains, has a most even and healthful climate. The annual mean temperature as compiled by Prof McAdie, for the U. S. Department of Agriculture, for three years past, shows 61.9, a temperature conducive to best results for agriculture, health and comfort. There is no frost to interfere with seed time nor the harvest. There are no driving rain storms to wash away the crops when grown and, with the exception of about three months of the year, July, August and September, will the daily temperature suggest to one the comfort of the shade of the gorgeous Umbrella tree or the graceful and luxuriant Elm, or Maple. Sunstrokes are unknown, diseases incident to the climate of the Middle West never appear in this locality, and as a result of the dry, bracing air, pulmonary complaints, throat troubles, asthma and kindred affections soon pass away from those who come bringing any one of them as legacies from the hot, humid climate of the East.

Statistics covering a period of ten years back demonstrate the mortality rate at 6.4 per thousand, while the birth rate shows one of the most productive regions on the Pacific Coast. Under the genial sun the farmer plants and always reaps. Some years in greater quantities, of course, than others, but never fails, because there are no contending elements nor unfriendly climatic conditions to conspire to destroy the fruit of his labor. We have been all over California, coming in at the north, going out at the south, criss-crossing the country over its mountains and through it fertile valleys and in all our ramblings we have found no place where the farmer can make as much money with as little labor as here in the San Joaquin valley, in the region of which we are writing.



Artesian Well Flowing into Reservoir. Has Been Flowing Twelve Years.

* * *

Wondrously Rich Soil.—We remember reading an article, a few years ago, from the pen of a distinguished eastern journalist who, in describing the soil of the San Joaquin valley, said it consisted of "one part earth and ten parts manure, and in that proportion was one hundred feet deep." Of course this was not literally true, but it was a statement which has enough of merit in it to challenge the attention of prospective buyers of California farm lands. The soil embraced in the region of which we write is of a peculiar character. It is composed of a deposit of sediment, tule roots, shells and silt, left by the receding waters of Tulare lake, which, according to the Government reports of 1880, covered it for a distance of several hundred square miles. You may dig down for twenty feet and this same peculiar soil confronts your operations. In point of richness, in producing power, the famous valley of the Nile is not its superior. You may crop these lands for fifty years incessantly and they will show no diminution of the elements which bring forth wheat, corn, alfalfa, in fact all the cereals in such amazing and satisfactory quantities. The grain fields in this territory in 1904 produced 60 bushels to the acre, while crops in certain portions of the tract went 76 bushels to the acre. The fact is that in grain producing quality and quantity the fields of the Tulare Lake region have startled the entire Pacific Coast and challenged comparison with the richest wheat producing sections of the whole world. Then there is alfalfa, the stockman's goal of prosperity. In 1904 from seventy-five acres, E. G. Sellers, of Lemoore, cut 300 tons of alfalfa hay from which he netted $1500. L. P. Denny, on a ranch of 300 acres, situated six miles south of Corcoran, Tulare lake section, in 1901 put up 1200 tons of first-class hay, also 5½ tons alfalfa seed, from 100 acres, of above. During winter of 1901-1902 pastured 300 head of cattle and 150 head of hogs thereon. Summer season of 1902 cut 300 acres alfalfa once and got 700 tons of hay. Pastured 400 head of cattle and 200 head of hogs remainder of that season and following winter. In 1904 this ranch increased its cattle and hogs and turned out approximately the same tonnage and seed tonnage.

I could multiply these instances of grain and hay production unlimitably—but it is not necessary. The potential fact remains, when all is written of this marvelous section, that it has no superior on the great Pacific Coast States.

* * *

The Stockman's Mecca.—I wish I could have had with me some of my stock raising friends of Iowa; men who, for thirty years, have done nothing but raise corn, where 40 bushels to the acre is an average big yield, where timothy and clover freeze out about every third winter, and where it costs today more than a third of what their cattle and a fourth of what their hogs bring in the market to finish them—I wish I could have had some of these men with me, as I rode through big herds of fat cattle and shiny porkers, to which never a pound of grain has been fed. Wouldn't I have made them turn green with envy? Why, last year, in Kings county alone, the shipping records show that nearly 800 carloads of fat cattle were shipped to the markets of San Francisco and Los Angeles. What may we not expect from this region when all the territory is occupied, as it will be in five or ten years, and men devote themselves to raising and shipping cattle and hogs for the markets of the world. Hogs of as fine class as any of our eastern stock are grown and fattened with almost no expense. They simply grow up, grow fat on the waste products of the soil, roll into the market and "roll the mortgage from the farm." The dairy industry in itself is an interesting proposition in such a country. The Kings county creamery alone paid the dairymen, last year, who sold it milk, $120,000. In Tulare county the record was about the same. The advantage the stockmen of this section have is in the absence of the diseases to which cattle and hogs in the East are subject. They mature their calves and pigs, they feed them on the richest of fattening grasses and hay, and get as much for them in the market as their brothers do who produce beef and pork at double the expense.

Great is the future of the Tulare district stock raiser. No wonder they wear diamonds and ride in autos, as the rancher did who whirled me over the country and shouted the praises of the San Joaquin valley until my head swam and I longed to be one of the "boys" again, astride a broncho, chasing the bounding steer.

Then there is the sheep industry. The annual clip of wool from 200,000 head of sheep brings in over $137,000 to Kings county. Tulare is in about the same proportion. The poultry interest comes in for its abundant share of credit in making prosperity for this community. It is a paying business, aided as it is by the equitable climate, which is conducive to the health of poultry.

* * *

I come to what appeals to me as the

potential factor in the development of this new region, and I may sum it up three words:

* * *

Magnificent Water Supply.—From eight to twelve feet the water plane underlying this whole section is reached. It comes down the shed direct from the Sierras, whose snow capped summits furnish never ending streams of pure snow water, which pour down into the valley and are lost in the sediment and silt soil miles from their source. It is this under-ground supply of soft water which furnishes the key to the prosperity of all this section. It is ever present, never ceasing, always to be had at command. Bore a well anywhere on the 35,000 acres of land in the Tulare Lake district and you will find water. This is the secret of the vast grain and alfalfa returns, which astonish the country. It is the secret of every success which comes to the prosperous farmer in all that region. At 650 to 900 and 1100 feet you strike the gushing artesian well, the water from which, when under pressure, spurts into the air a distance of four to twelve feet sending out such a volume as will irrigate without difficulty, a quarter section of land. Wells sunk at a depth of 60 to 150 feet furnish abundant water for irrigating small ranches at a very moderate cost. So it will be seen that the question of water does not disturb the people of Kings and Tulare counties, whose future along this line is amply secure.

* * *

New Town of Corcoran.—Along the western part of this newly developing section a nice town is in process of construction. Although not over sixty days have passed since it was laid out, several hundred thousand dollars in substantial improvements in and around the town are under way. Within twelve months the visitor will see one of the most up-to-date farmers' towns in California, equipped with every appointment essential for the comfort and pleasure of a prosperous people. Parks, boulevards, electric lights, fountains, wide avenues, brick and stone buildings, churches, school houses, bank, newspaper and commercial houses for general purposes, will stand out against a background of green foothills, a picture of beauty and an ever present reminder of the energy and ability of the men who have builded it. But of this new city, with all of its thrift and beauty and enchantment, we can not speak further at this writing. At a later day it and the fruit interests around it, will call for extended comment. Great things "are doing" now in this Eutopia of the Golden State. The men who, by their brain and energy, are building up a new enterprise on the waste of a once great lake, will create a monument to the genius of their spirit to which future generations may point with splendid satisfaction. Of such men was the Republic builded.

* * *

Some Data.—In a circular issued recently, the Security Land and Loan Company make the following statement relating to agricultural interests in the Tulare Lake District country. We quote:

"This is a section of intensive and diversified cultivation made possible by the rich soil, constantly-stimulating sunshine and plentiful water supply.

Peach orchards frequently yield from $40 to $100 net per acre. Vineyards produce from $60 to $120 per acre, and many wheat fields yield from 25 to 60 bushels per acre.

Kings county stands in the front rank as to variety of products grown in sufficient quantities to be shipped in carload lots—56 distinct varieties being the record for last year.

The following list of products of the soil gives an idea of the comprehensive possibilities:

An Artesian Well Near Corcoran.

Diversified Products Shipped From Kings County.—Alfalfa hay, alfalfa seed, almonds, apricots (green and dried), apricot pits, assorted canned fruits, (apricots, peaches, nectarines, plums and grapes) barley (ground and whole), barley hay, bees, beans, bran, brandy, bucks, bulls (breeding), calves, cattle (beef), corn, cows, (dairy), dairy products (butter, cheese and condensed milk), flour, grape cuttings, grapes (green), hides, hogs, horses, honey, mules, peaches (dried and green), peach pits, pears, plums, potatoes, prunes, raisins (loose and seeded), sheep (mutton and range), trees (nursery stock) wheat, wheat hay, wine, wine pomace, wool.

A Bunch of Kings County Porkers.

BEET SUGAR ENTERPRISE.

In the Los Angeles Times of August 5, 1905, appears the following in reference to the beet sugar industry:

"Another regular source of income for the small farmer will be provided by the beet sugar factories. One of these is now in course of erection close to Visalia, and others are projected, for experiments have proved that beets of the finest sugar-producing quality can be grown throughout Tulare and Kings counties. Moreover, owing to the length of the season in this sunny land, delivery of beets will be possible from June to October, a run of five months. The factory at Visalia will contain the most modern plant, and its capacity will be 300 tons per day. Contracts with beet growers are now being arranged—that is to say, the farmer will have the guaarntee that all the beets he grows will be taken off his hands at a fixed price for a series of years. In a district where there is such diversity of products there is little chance of the beet grower being ground down to an unremunerative figure, and such factories will exercise a healthy stimulus in competing with the wineries for the acreage available. Thus the city of Visalia has shown judgment and foresight in freely donating forty acres as the site for the first beet sugar factory, while the individual citizens have given the very best proof of local faith in the enterprise by subscribing $50,000 of bonds. When communities come forward in this way to help themselves, the confidence of capitalists is strengthened a hundred fold.

* * *

The Problem of Foothill Irrigation.—It has already been mentioned that, while a number of the citrus belt orchards are irrigated with ditch water, most of them depend exclusively on pumping. As regards subterranean supplies, the general proposition holding good throughout the length and breadth of Tulare and Kings counties is that you may bore a hole anywhere with the absolute certainty of striking water. Splendid rivers, indeed, have their courses over the surface of the soil, and with their network of irrigation channels cover the land like the venation of a leaf. But still vaster bodies of water flow continuously underground from the mountains towards the great central depression of the country, the old Tulare Lake bed. Along the foothills good irrigation wells can be got at a depth of from 50 to 60 feet.—Los Angeles Times.

* * *

THE PROLIFIC HOG.

Every successful farmer in the Middle West knows what a good hog is, and the country where swine will do well and grow to perfection and grow fast takes his eye. Well, among the fifty-two articles of products shipped out of Kings county by carload lots, is the hog. From Hanford during the last year four hundred carloads of fat hogs were shipped. These hogs were raised on alfalfa, skim milk, whey, pumpkins, barley, wheat and corn. The breeding of thoroughbred swine is becoming general and the favorite breeds are Poland China, Berkshire, Durocs. The black or brown hog does the best here, and stands the climate and thrives. The 400 carloads referred to here and as the output from Hanford the past year, averaged 17,000 pounds to the car, making 6,800,000 pounds, and the average price paid to the farmer was 5½ cents, which would bring the total amount to $374,000.00, for hogs shipped from the Hanford station alone. We have not the data from Lemoore, Armona and Guernsey. —Hanford Sentiuel.

* * *

REFUND TO PURCHASERS.

In June an important decision was made in the Supreme Court, whereby $71,000 will be refunded by the county treasurer to purchasers of 137,000 acres of lake lands. A number of suits have already been brought to trial, and in each case a writ of mandate has been issued in favor of the plaintiff and against the county treasurer.—Hanford Journal.

About twenty thousand eastern brook trout has been planted in Middle Tule river, Tulare county.

C. H. SESSIONS, ASSOCIATE EDITOR

THE MOTTLING OF BUTTER.

The general teaching of today about the mottling of butter is well summarized by Mr. H. Hayward in circular 56 of the department of agriculture, bureau of animal industry, entitled "Facts concerning the history, commerce and mnufacture of butter;" and we quote from this circular: "One of the serious defects often found in butter is lack of uniformity of color, or what is commonly known as 'mottles.' This defect is seen in white streaks, spots or blotches, which are most pronounced when a lump of butter is cut so as to show a broad, smooth surface. If this cut surface is held at a proper angle to the light, any lack of uniformity in color will be plainly noticed. So serious is this defect considered that butter otherwise perfect, but mottled, is graded as second class in the large markets. The causes to which this fault can be attributed are, first, particles of curd, differing in size, incorporated in the butter, and second, an uneven distribution of salt. Mottles in creamery butter are seldom caused by specks of curd, but in the poorer classes of dairy butter this kind of mottles is not infrequently seen. They are most likely to occur when the cream from which the butter is made is thin and allowed to ripen without being stirred, or when it is over-ripened without being strained. The cream being churned under these conditions, lumps of coagulated cream are incorporated in the butter, and as the casein does not take the butter color the result is a product full of white specks. When the trouble is caused in this way it can be obviated by washing the butter twice in a weak brine after the buttermilk is thoroughly drained off. After the last washing, instead of draining the brine from the butter, as is usually done, the butter should be dipped out of the brine with a hair or wire sieve; the specks of curd, being heavier than butter or water, will have sunk to the bottom of the churn.

"Most of the mottles found in butter, however, are caused by an unequal distribution of salt. When the wash-water is considerably colder than the butter granules the exterior of the latter become harder than the interior; this prevents an equal absorption of the salt when the butter is salted and worked, and mottles result. Also, when thin cream is churned at a low temperature the butter usually comes in round, shot-like granules; on account of being round and quite firm it is with difficulty that the salt is equally distributed and, unless great care is exercised, the finished butter is mottled. Of course, if under the most favorable conditions the butter is not worked enough to distribute the salt equally, mottles will be noticed in the finished product.

"Mottles may be prevented, then, by avoiding high temperatures in ripening cream, by frequent stirring during ripening, by straining the ripened cream into the churn, by avoiding exposure of the butter to temperatures too low while in granular form (which causes a difference between the interior and exterior of the butter-granules) and by working the butter sufficiently to cause an equal distribution of the salt."

It is very noticeable that in all the dairy literature which has come to hand there is no suggestion that the proteids present in the cream have any connection with mottles in butter, except the single form which comes from curdled casein specks or particles; but this form is of so infrequent occurrence, compared with the other form, that many teachers do not apply the term mottles to the discoloration caused by curd particles. It is to the other form of mottles that we have given our attention, that is, the form characterized by light-colored streaks, waves or large patches. It should be stated that Prof. C. F. Doane of the Maryland agricultural college considered the relation of casein (casein lactate) to mottled butter but concluded that this proteid had no relation to the light-colored streaks of mottled butter.

Prof. Storch appears to attribute the formation of mottles to an excessively large number of minute liquid drops of what he calls "water mucoid substance," the difference in the size and number of these liquid drops being caused by the action of special microorganisms during the ripening of cream. This theory lacks satisfactory demonstration and has not been received with favor. Much valuable information on the subject was recently gained through the New York Produce Review sending out a series of questions and securing replies from many of the most prominent teachers of dairying in the country. It is impossible, for lack of space, to give the information in full, but good summaries are given herewith following each question:

Does mottling of butter occur at one particular time of year more than another? If so, when and why? In most cases it is reported that mottling occurs more frequently in cold weather, because it is more difficult to distribute the salt evenly through the butter, owing to the lower temperature of the wash-water and the greater firmness of the butter.

What different kinds of mottling do you recognize? There is considerable variation in the replies made to this question. Summarizing all the different statements, the question is answered as follows: (1) An uneven distribution of color showing in small patches, (2) streaking or wavy mottles, (3) white specks, and (4) dapples. In most cases the expression indicates only one kiud of mottling but varying in form and showing as streaks, waves or cloudiness.

What do you regard as the cause of mottling? Every reply indicated the uneven distribution of salt in butter as the chief or sole cause of mottling.

TUBULAR--or "Back Breaker?"

When you see the waist low Tubular you can't be driven into buying a back-breaking, "bucket bowl" separator. **Can and crank are just the right height on the Tubular.** Here is the largest Dairy Tubular along side four "back breakers." The girl with her hand on the Tubular is 5 feet, 4 inches tall. This is an exact reproduction from a photograph. **Which kind for you?** Makers of "back breakers" try to get their cans low by setting the cranks low. **High cans** break your back backward—**low cranks** break it forward. Unless you are a double jointed giant, you'll find a high can is no joke. To show you how high these "back breaker" cans really are, when the machines are set high enough to turn easily, we raised these "back breakers" 'til their crank axles were level with the Tubular crank axle. "Back breaker" makers don't like this picture—**it's too true.** They try to squirm out of it. **You wouldn't like turning cranks as low as "back breaker" makers put them.**

The low can is only one of many advantages Dairy Tubulars have over all others. Dairy Tubular bowls are simple--"back breakers" are complicated. Tubulars are self-oiling--no oil holes to fill up. "Back breakers" are oil drippers and oil wasters. To learn a lot more about Tubulars, write today for catalog N-260

When writing advertisers mention Cultivator.

Additional or contributory causes are given as follows: (1) Uneven cream-ripening, (2) pasteurizing sour cream, (3) insufficient working, (4) chilled granules worked too soon.

Has ripening of cream anything to do with mottling? If so, how? The general opinion is that cream-ripening has no relation to the mottling of butter, except that white specks in butter are often caused by over-ripe cream.

Does the temperature of churning influence mottling? The general belief expressed is that churning has little or nothing to do with mottling. The following special suggestions are made: (1) Some temperature conditions of churning make difficult the even distribution of salt and so contribute to mottling. (2) Too low or too high churning temperature may interfere with proper working of butter and consequent distribution of salt. thus favoring the formation of mottles. (3) If butter is made too hard the salt cannot be easily distributed uniformly. (4) Over-ripe cream churned at too high temperature produces mottles. Summarizing these statements, it is the prevailing belief that the temperature of churning may affect the mottling of butter, when the uniform distribution of salt is made difficult, especially churning at low temperature.

Does the temperature of the wash-water influence mottling? Some state that the temperature of the wash-water has no influence upon the mottling of butter. Several hold that the use of water so cold as to harden the butter considerably would cause mottling by preventing the uniform distribution of salt. One states that mottles are produced whenever the wash-water is colder than the butter. Another claims that mottles are unusual when the wash-water, salt and butter are of the same temperature.

Does the size of granules influence mottling? The general belief expressed is that there is no relation between the size of butter-granules and mottling. One states that large granules, when hard, favor mottling; but, when the butter is soft, the size of granules makes no difference. Two state that small granules are preferable since large granules favor mottling.

Does salt influence mottling? The expression is unanimous that the uneven distribution of salt is the chief, if not the sole cause of mottling.

Has the butter color used anything to do with mottling? All state that butter color properly used is not, in their experience, ever a cause of mottling.

Can you effectively control the mottling of butter? If so, how? Summarized in the briefest expression, the belief of all is that mottles can be prevented hy proper working of butter, that is, by effecting a complete and uniform distribution of salt through the mass of butter. Described in more detail, the even distribution of salt and the resulting control of mottles can be accomplished by churning between 52 and 55 degress F. to granules the size of wheat grains, drawing off buttermilk, washing once with water below 50 degrees F., draining, salting and allowing to stand 2 to 4 hours before working.

What is your theory in regard to the mottling of butter, that is, the causes producing it and the manner in which they produce it? All answers agree in assigning as the main cause of mottles in butter the uneven distribution of salt or brine as the result of insufficient working. The manner of production is generally explained by the statement that salt or brine intensifies or deepens and so changes the color of butter, the light parts containing less salt or brine than the darker portions. One holds the belief that there is more moisture in those portions of hutter containing more salt and this produces change of color.

Are buttermakers in your section troubled with mottling so far as your observation goes? There is more or less trouble, but less than formerly, owing to the better education of buttermakers.

HOW TO GET $100 COWS.

Buy, if you can, but they are rarely met. They are seldom recognized when met. They are never for sale when recognized, says Hoard's.

To raise them begin with the grandam. They must be adapted to your purpose and conditions. The bull is the largest factor in breeding, and should be the object of greatest solicitude in selection. He should come from stock of typical symmetry and demonstrated capacity. The cows should be tidy and typical rather than big performers without good form. Do not scruple to inbreed if your bull is better than the one you are likely to replace him with.

Just one word more. In a great many instances, the cow is made or unmade by the way she is fed and handled the first years of her life. A man who understands how to handle the heifer from calfhood up till she is well established in her growth, say at 15 months of age, has a great advantage over the ordinary farmer in the production of cows. We would pay considerably more for such a heifer than for one handled as the average farmer treats his young stock.

Many a good horse is spoiled, as far as looks go, if not more, when he gets the habit of rubbing out his mane and tail. This practice is not really a habit. Lack of exercise, as well as overfeeding, causes the trouble, and especially so where the animal is kept in a badly ventilated, dirty stable and not groomed daily. Stop feeding grain. Exercise or work every day and groom thoroughly each day. Dissolve two tablespoonfuls of glauber salts in drinking water twice daily. Wash the tail and mane thoroughly every other day with a 1-50 solution of coal tar disinfectant or dip.

The important features of a dairy cow are: (1) udder capacity, (2) size of barrel, (3) form of hind quarters, (4) head, neck, shoulders, (5) skin, hair, veins and escutcheon. Yet, in spite of the best outward indications, you often get fooled on the actual performance.

A FARMER'S OPINION.

My family must learn which is the best washing machine, the purest coffe, the best dress goods, etc., through the advertisements in my farm paper. I expect these ads to give as truthful descriptions of the articles for sale as an honest clerk would if we were shopping in some large city store. We haven't the opportunity to look around at different stores; we must buy mostly from advertisements.

Now, some advertisements don't look honest.

No farmer expects to get a set of harness free with every $3.00 pail of stock-food. We know somebody has got to pay for that harness—and we don't expect "something for nothing." We are perfectly willing to pay for what we get, but we do expect to get what we pay for.

The advertising that strikes me is the kind the "Security Stock Food" people do. They give a spot cash guarantee that their stock food will do certain things and that their remedies will be successful. They don't claim the earth or absolutely promise to cure every disease known to farm animals. But they do say in every advertisement and on every package sent out, "If not satisfactory, we will refund price in full."

That's the kind of advertising I believe in. If any one differs from me, let him send his ideas to the publishers of this paper for publication.

The Doke Stock Food Co., 2812 Central Ave., Los Angeles, has engaged Mr. R. R. Grant who will act as traveling representative commencing Oct. 9. This company has an excellent stock and poultry food which is meeting with good success. Write them for circulars and testimonials.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

BE FAITHFUL.

"Sois fidele" (be faithful) was the motto for about a thousand years in the family of a little girl. Faithfulness in little things was inculcated in her family, but whether inbred in her or not, faithful she was as a little mite of a child, and especially toward living objects, her pets.

She was a frail little thing, the eldest of six children; but she was faithful; her brothers relied upon her, brought her all their pet animals, squirrels, mice, guinea pigs, kittens, birds of all kinds, taken from nests, as boys will do, finches, bluejays, meadow larks, blackbirds, thrushes, doves and even owlets. The little mother ten years old cared for them all according to their various needs. She searched the encyclopedia of natural history, finding in it the natural food of each different species, and endeavoring as far as possible to supply their natural food and imitate it closely. From sunrise (and the sun rose very early in those days) to sunset, every two hours "little mother" fed her charges. "Just three beaksful apiece," she said, "is the rule." The owlets were quite a trial to her, as their food was mice, but she visited the village store and purchased eight large thimbles, borrowed eight bowls from the cook and as many plates, she then stuffed each thimble full of cheese, set a thimble on a plate putting the edge of the inverted bowl on the edge of the thimble so that, when the mouse went under the bowl to partake of the cheese in the thimble, as soon as it began to nibble the thimble shook and the bowl slipped down imprisoning the mouse under the bowl, which was then immersed in a bucket of water.

In this way little mother supplied the mice for the owlets, but the boys were required to cut them up and assist at the feeding, for the owlets seemed to prefer little mother's fingers to the mice, and although she was ready to make every necessary sacrifice for the comfort of the solemn looking, flabby, little owls, she could not spare her fingers. The boys soon found the duties of caring for the little owlets more onerous than they anticipated and the three wise baby birds were carried back to the hole in the big oak tree which had been their home with a supply of mice for their supper to be administered by their own parents. When the other birds were full grown and able to fly the boys, their owners, claimed them and little mother regretfully gave up her charges. This was for years an occurrence every summer in the life of little mother, but during this time she had also pet canaries of her own, besides a squirrel, kitten, pony, goat and cow. There were chickens, ducks, turkeys and swans on the place, and although she had no charge of them they all knew her and loved her; she was the one to rescue the old hen who had jumped or flown into the pond after her brood of ducklings, and whenever there was trouble of any kind in the fowl yard little mother was generally to be found mothering the unlucky ones.

As she grew older she developed a large flock of canaries and the same faithfulness to them and study of their needs resulted in the same success.

When she become a trained nurse the same faithfulness went through life with her, so that no patient was neglected, her duties were never forgotten. Later on in life when she

Used by all the largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Hap-hazard feeding is no longer profitable. Try Midland Food and be convinced.

PETALUMA INCUBATORS
—AND—
BROODERS
The acknowledged standards of perfection. All poultrymen who have used these machines have supreme confidence in their ability to hatch and brood. Hence their ever increasing popularity. Winners of the GOLD MEDAL at the St. Louis World's Fair for greatest hatch, with 40 different makes of incubators in competition. How's that?
St. Louis, Mo., Dec. 8th, 1604.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A FILCHER, Commissioner.
Sumptuously illustrated catalogue free; write for one at once. Send for our poultry supply catalogue No. 47, describing our line of supplies. Everything for the Poultrymen.

went into the poultry business, as a business, she was especially faithful and was one of the "lucky" ones who made a success of it from the very beginning, just by being faithful in little things. I think she is lucky; she claims that she is, but it is a good deal owing to patient, persevering faithfulness that brings her good luck.

Now I sometimes feel as if you all will get tired of my talking about little things. Life, and especially chicken life is made up of little things.

"Little drops of water,
Little grains of sand
Make the mighty ocean
And the pleasant land."

* * *

In my talks on roup and on summer care I have tried to emphasize the needs of fresh, pure water for fowls; keep the water pure and cool; it pays to lay a water pipe to the poultry yard, even to lay it above ground if you cannot put it under ground.

And then the "little grains of sand." Sand or grit is a mental characteristic of a successful man, and sand or grit is an absolute necessity for a successful hen. There are but few poultry ranches, and no poultry yards that have a natural supply of grit sharp enough or sufficient enough to supply grit or teeth for a flock of thrifty hens. Give them grit if you want them to lay eggs; give them a plentiful supply of grit, shell and charcoal.

Next time I will tell you of the evil effects of giving lime instead of grit. Just now I am at Portland and friends are waiting to take me to the exposition, so I will bring this letter to a close.

Later on I want to talk of some of the little things that cause us to have bad hatches, but it is rather early in the season for that.

POULTRY QUESTION BOX.

In the absence of Mrs. Basley, general information is given in answer to a number of inquiries which have come during the past week, though some will be more fully answered by Mrs. Basley on her return from the North.

* * *

Editor Cultivator: What is pip in chickens, the cause and the cure?—M. L. D., San Martin.

Pip is the result of a disease, rather than the disease itself. It is a drying of the tip of the tongue and the forming of a hardened coating. Some advise treating the tongue with glycerine, others picking off the hardened coating, though this is not exactly according to the best authority. If it comes from roup or catarrh or other condition which causes more or less fever about the head and breathing through the open mouth, treat those diseases according to the formulas given by Mrs. Basley in former issues of the Cultivator.

* * *

DUCK FEED.

Editor Cultivator: What proportion of corn meal, bran and beef scraps will make best feed for Indian Runner ducks? Should it be fed wet or dry? Is sand or grit necessary? Ducks just commencing to lay. Have range on alfalfa.—M. E. M., Santa Ana.

Equal parts meal and bran, ten per cent of beef scraps and perhaps five per cent grit. The addition of cooked carrots or other vegetables is advantageous.

* * *

MELONS FOR CHICKENS.

Editor Cultivator: Will it injure young chickens if they eat melons?—Subscriber, Lompoc.

Too many melons might result in diarrhoea, but if fed in reasonable quantity they make a good addition to poultry rations.

* * *

ROUP HEREDITARY.

Editor Cultivator: Have had serious trouble with roup this season. Is there danger of chickens hatched from these eggs inheriting tendency to disease?—V. B., Santa Ana.

While it is not probable that the disease is directly hereditary, it goes without saying that hers which have been seriously diseased have lower vitality than those which have been thrifty all their life. If the hen has lower vitality, the egg has also, so that the resulting stock would be less hearty and more subject to disease We would advise using your eggs for market purposes and securing from the strongest and thritiest stock possible fresh eggs and when the young are hatched would keep away from runs of last year's flocks, if possible to do so. If not, thorough disinfection and every precaution to protect from draughts, moisture and other bad conditions, should be taken when next year's birds are hatched.

* * *

SEX OF CHICKS.

Editor Cultivator: How old should White Leghorns and Plymouth Rock chicks be before allowing to roost on poles? Do not wish crooked breastbones.

How can I distinguish the sex of small chicks? At about what age should they be separated?—F. J. E., Escondido.

The Leghorns being lighter weight may be allowed to roost on poles younger, say at two months, but the heavier breed should be at least three months.

The comb and size of the head are the only ways of determining sex of the very young, and some claim to be expert enough that they can separate the sexes a very few days from the shell. The comb and head of the male is almost invariably slightly larger, though it takes considerable experience to be infallible in determining the sex of the very young chickens. They should be separated while quite young, especially if the runs are small. If before two months old, it will be well.

Poultry pays more in proportion to the amount of money invested than any other stock on the farm. There is no reason why the department of poultry on every farm should not be systematized as to apartments, regular care and attention, as well as that of cows, horses and sheep. If you neglected your cows or your horse as many farmers do their poultry, you would soon be a defendant in a suit for foreclosure, if you arn't already.

A Visit to the Large Packing Houses in the Eastern Cities

In Three Chapters.—Part III.

BY A. R. COULSON

AT CHICAGO

Chicago, Ill:. is the greatest business city of the world today. In Chicago you see great, monstrous buildings, a whole block square and perhaps twenty or thirty-five stories high; and occupied by one store, or owned by one firm. Sometimes one firm will occupy several of such buildings and employ thousands of persons.

The shopping district of Chicago is the most congested in the world; this is probably due to the scheme of street car transit, to bring people from all directions to one center. Consequently the stores had to be built both up and down, that is deep foundations, allowing four or five stories underground and twenty stories or so above ground.

The head offices of many of the largest business firms and the greatest commercial institutions in the world are invariably located at Chicago.

The Meat Packing business, the greatest industry in the country, is an industry whose six leading exponents turn out a product exceeding the United States Government income.

It is the only business in the world that shows a loss on its main product, and still draws a profit on its entire operations—because it has measured the value of waste material, and found use for all.

This is the Packing House business, whose "Big Six" do a business of $700,000,000 a year and represent an invested capital of $90,000,000, employing 200,000 persons, and supplying the whole civilized world with food products.

While I was in Chicago I went over to La Salle street to the head offices of the Armour Packing Co., a ten-story office building, and on each floor are offices devoted to special departments of the business. As I was interested in doing business with the Animal Food Departments, the general office of which was on the tenth floor, I got in one of the elevators, and in about three seconds, I was shot up and out on the tenth floor.

I gave my card to one of the messengers, and was taken into the private office of Geo. C. Vernard, who is the manager of the Fertilizer and Animal Food Department at the Union Stock Yards, Chicago, and is also General Manager of all other branches located in the different cities. Mr. Vernard was formerly at the Kansas City plant, but on account of his good judgment and good business management, he was promoted to the head office and given authority over the Fertilizer Department of all the other plants.

We went out and had lunch in one of Chicago's swellest dining rooms, and then we got on the Lake Shore train and went out to the Packing House Plants at Union Stock Yards, Chicago. (See illustrations.) In order to get a photograph of the immense works here, it was necessary to go up in a balloon and the photograph was taken from a balloon at an elevation of 750 feet above the ground.

The development of the methods of meat preparations has been marvelous. The new methods and large establishments have been the outgrowth and gathering together of many small shops; thus today instead of small butchers, we have large packing houses caring for many thousands of cattle, sheep and hogs per day. This has brought about reforms almost impossible had the industry been left in the hands of the small butcher. Sanitary care of the products, the utilization of every portion of the animal and the cheapening of the cost of meat is the result.

They understand the necessity of the rapid disposal of the numerous portions of the animal anatomy; the prominent idea being to do the work as cleanly, carefully and as rapidly as possible.

In the actual slaughtering operations, three features of economy are evident; the use of labor saving machinery, the subdivision of and specilization of labor, and the use of every part of the animal to the highest advantage.

The by-products have made the Packing House Industry possible, has built up vast stock yards and great Packing Towns; and has developed the great West into a settled country of stock raisers and corn growers and has given the people of the world fresh meats.

Balloon View of Armour's, the largest Packing Plant in the world. Photographs taken from a Balloon at an elevation of 750 feet. This is one of the plants that furnishes the Coulson Poultry and Stock Food Co. with Hearts and Liver Meat Meal, Dried Blood and Ground Beef Scraps, etc. for making Coulson's Poultry Foods.

This is why the packer is today the captain of industry, and of many industries. One of the packing house firms, for example, conducts as many as sixty-eight different businesses in different cities; and as far as possible, each one of these sixty-eight, or more businesses in a packing house, is conducted on an independent basis. It has its own place in the Packing House proper and its own office force in the general office, each department is expected to show a profit in its operations. All these different departments are made to pull together by means of a General Manager, located at the head office at Chicago, who gives instructions to the managers stationed at the factories.

The animals walk to the Packing House on their own feet, and are driven to the knocking pens as required. After being stunned by the knocker, they slide down into another department, where they are shackled with chains, and hung up on rails, which are fitted to the ceiling of the packing house. They are like inverted railway tracks, and they slide along on wheels. From the time the steer is hoisted to the rail on the killing floor until the time he is shipped as dressed beef, several days later, he never leaves the rail; as by means of a switcher the animal can be sent to any part of the plant. There are more than ten miles of these rails in the Chicago plant.

It takes 126 men to slaughter an animal, 126 individual operations are performed from the time it leaves the pen until it travels to the cooler. Each man is trained to do one particular thing—one man skins a fore-leg, another man some other part, etc.

The Hearts and Livers are kept out in a pile by themselves. These are cooked and baked in big boilers and furnaces, and are made into Hearts and Liver Meal, which is shipped out in carload lots to the Coulson Poultry & Stock Food Co., at Petaluma, California; and they use it in making Coulson's Special Dry Chick Food,

View of the General Office of Armour & Co., at the Union Stock Yards at Chicago.

which is said to be the Greatest Feed in the World to make Little Chicks Grow and keep them healthy.

The live animal, before entering the slaughtering house has undergone the State, City and United States Government Inspection. Fourteen days after the animal is slaughtered it is ready for sale in England, and by simple refrigeration the meat is kept bright and fresh.

In the cutting rooms you see hundreds of men carefully carve out the various portions. One might be cutting meat for the English market, another for the Belgium trade. The meat products are sent to nearly all countries of the world. Barreled pork to South Africa, Bacon to Finland, Norway and Sweden. Then there are the Canned Meats, one hundred varieties, and sausages, not only for home consumption, but also for Porto Rico, Cuba, France, Germany and Belgium. A production of 100,000 pounds in a day is often made. Then there are the extracts of beef, chipped beef, lard compound, lard oil, butterine, mince meat, plum pudding and hundreds of other things.

The utilization of this formerly waste material can only be accomplished where stock is killed in large numbers, as the plants for taking care of such products are very expensive, and beyond the reach of the small slaughter houses.

This is why Armour Co. are in the best position to make the best Animal Foods, for they can handle it while it is fresh, and prepare it in better shape, and this is why the Coulson Poultry & Stock Food Co., have contracted with the Armour Packing Co. for the Animal Meals which are used in preparing Coulson's Egg Food and Coulson's Chick Food, etc.

The Dried Blood is collected as soon as the animal is killed and it is cooked and evaporated and made into Dried Blood Meal. This is then put up in bags and used by the Coulson Co., in making Coulson's Foods.

The Hearts and Livers from all the animals are cooked and baked and made into meat meal and shipped to the Coulson Company, and this is one of the reasons why Coulson's Special Dry Chick Food gives such good satisfaction.

All the beef scraps that are made at this immense plant, also all the Beef Scraps that they make at Omaha Kansas City and St. Louis, are shipped out in carload lots to the Coulson Poultry & Stock Food Co., at Petaluma, California, and these Beef Scraps are sold to the poultry men of the Pacific Coast at from $3 to $3.50 per hundred pounds, according to the quantity purchased, etc.

But almost the entire quantity of Hearts and Liver Meal is used by the Coulson Co., themselves, in preparing Coulson's Egg Food, a mixed feed to make hens lay; and COULSON'S SPECIAL DRY CHICK FOOD, the greatest feed ever made to promote the growth of baby chicks and turkeys.

There are many other Poultry Foods on the market which the merchant will tell you are cheaper than Coulson's—but for the small difference of 10 cents or 25 cents on a sack, it will pay you to get Coulson's every time.

$500.00 to be given away. Look for Particulars in every 100lb sack of Coulson's Special Chick Feed.

COULSON'S SPECIAL CHICK FOOD.

Contains ingredients that long experience in poultry raising has found best adapted to give nourishment to growing chicks. It is promptly digested; causes no indigestion; keeps bowels in normal condition. Chicks show increase in weight, strength and beauty when fed it exclusively. Little chicks need no other food for the first five or six weeks. Save your chicks and make good profits.

It goes further than any other feed, as it is all good substantial feed. You can feed it to chicks the first four weeks at a cost of 3c per chick. The second month at a cost of 5c per chick.

You will have the best success you ever had in raising Chickens if you will feed COULSON'S SPECIAL DRY CHICK FEED. Send for sample. It's good for turkeys as well. Ask your dealer.

View of the entrance to the Union Stock Yards, Chicago. The Hearts and Livers from the animals are cooked and baked and made into Meal and are used by the Coulson Co., in making Coulson's Special Chick Food.

Scraping, Cleaning and Dressing hogs preparatory to going into the cooler. Man in black U. S. G. Inspector.

Coulson's Special Chick Food

If you want to see chicks dive into the feed as though they like it; if you want to see the little chicks always spry and healthy, if you want them to grow rapidly and mature quickly, then feed them

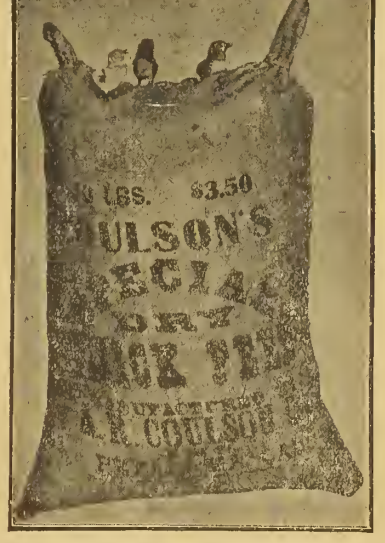
Coulson's Special Chick Food

and you will be pleased with the way your little chicks are growing. No bowel trouble, no weakness amongst the chicks if they are raised on

Coulson's Special Chick Food

for it will raise the finest and largest chicks.

$500 in Prizes



A Train Load of Coulson's Special Chick Feed was used in California last season—800 stores sell it. A great many stores will try to sell you some other kind. Insist upon having Coulson's Special Feed, for your success may depend upon it. Remember, YOUR success, not his.

WHAT A BOY CAN DO.

These are some of the things a boy can do:
He can shout so loud the air turns blue;
He can make all sounds of beast and bird
And a thousand more they never heard.

He can crow or cackle, chirp or cluck
Till he fools the rooster, hen or duck;
He can mock the dog or lamb or cow,
And the cat hersedf can't beat his "meow."

He has sounds that are ruffled, striped or plain;
He can thunder by like a railway train,
Stop at the stations a breath and then
Apply the steam and be off again.

He has all of his powers in such command
He can turn right into a full brass band,
With all of the instruments ever played,
And march away as a street parade.

You can tell that a boy is very ill
If he's wide awake and keeping still.
But earth would be—God bless their noise!—
A dull old place if there were no boys.
—Christian Endeavor World.

The Valley Between.

The Spur Mountains belonged to the Macdonalds, and the Lonnon Mountains to the McAllisters. The valley between them was no man's land, for they were too busy fighting over it to keep the thieves from the hills. They had fought year in and year out for longer than the memory of man, and neither boasted long of advantage, till the days when Robert McAllister, seventh of the name, grew old. Then an ill time happened to the clan. His eldest son slipped over a crag and was killed. His second and third sons were slain, away in the wars; and the youngest son died in his bed of some womanish complaint—a hard fate for a brave man. Since Robert McAllister was too old for arms, the name of the clan grew small, and the more daring of the tribesmen took service abroad under the king of France; for Mary McAllister had the spirit of a man, but the body of a maid.

Alan, the young chief of the Macdonalds, had won great renown in arms, and he had the way of leading men; and those who are born for leading never lack men to lead. He drove the McAllisters from the valley, and built little fortresses there to hold it, and when he had held it for a full year he sent a message to Robert McAllister, saying that further strife was vain, and offering terms of peace if they would own that the valley was his.

Thereupon the McAllisters gathered together and made a great raid, taking away cattle in hundreds that were in the valley to graze, and razing one of the little fortresses to the ground. The week after, Alan Macdonald fell upon them and took back about fourfold. And afterward he sent a piper with a letter, which read like this:

"From Alan Macdonald to Robert McAllister, most courteous greetings.

"The fortune of war has given us advantage which you cannot resist. When strife is useless, strife should cease. If you will own that the valley is mine, I shall be honored by your using it. It is said that good foes make good friends, and I am wishful to try; for there is none who honors your name more than I."

Robert McAllister, being a wise old man, was mindful to consent.

"It is a generous offer from a gallant enemy," he said.

But his daughter pleaded with him in her dead brothers' names and prevailed. So he made answer thus:

"Robert McAllister sends all courteous greeting to Alan Macdonald. The fortune of the moment changes. For those who come after, I hold to what I have held and my forefathers before me. If our numbers are lessened, our courage is not."

Then came another message from Alan Macdonald:

"If you rely on courage, let one of your tribe meet me in single combat, the valley to belong to the victor's clan.

Alan Macdonald."

Many of the McAllisters volunteered for the fight, but there was no great man of arms among them, and the elders would not consent.

"It were giving Macdonald the land," they declared. "There is no man in Scotland who can stand before him." For he was a large, powerful man, and withal quick as smaller men are; and had a curious cunning of fence which he had learned in France.

So they sent no answer at all, and Mary McAllister locked herself in her room for two days, and brooded over the dishonor of her clan. Presently she made a deep plan, as women will do, and rode out in the gray dawn to the castle on the Spur Mountains; and when Macdonald's outposts challenged her in the valley, she answered:

"I am Mary McAllister, and I have come to answer the challenge of your chief." Then they sent a guide to conduct her the easiest way to the castle, and when the chief warder came to the gate and asked her pleasure, she made him the same answer as before.

After he had stared at her once for her daring and twice for her beauty, he conducted her to a great hall; and Alan Macdonald rose and came to meet her, and set a chair, and stood with his cap in his hand, marveling that any woman should be so fair; for she had pale-blue eyes and red-gold hair, and her face was like a wild spring flower.

"You honor me greatly," he told her. "Have no fear." She laughed carelessly.

"I had no fear," she said, and he bowed.

"Fair lady, you honor me more."

"It was not for your honor I came, but for the honor of my clan, and my own." He bowed again.

"There is no dishonor in peace," he said.

"Neither have I come in peace." He caught a look in her eyes that he had seen in the face of a foe before, and he knew that she spoke no light word. Wherefore he became very grave.

"War is not for women," he told her.

"I had not come if any of my brothers had lived; but perchance"—she tossed back her hair that was like red gold—"you had not challenged us then?"

He flushed hotly. "Think you so?"

Their eyes met for a moment, and she smiled suddenly. There was a year's spring, it seemed to him in her smile.

"Nay," she owned, "I think not so. Alan Macdonald, you fear no man." He laughed a soft laugh.

"I have feared no woman till now." She put her head back and looked up at him.

"Fear you me?"

"As a man may fear."

"Fear you my challenge?" He knitted his brows in thought before he spoke.

"Name what champion you will," he said at last. "I will meet him, if he is not your lover. Believe me,"—there was a sudden depth in his voice—"I would not earn your hate." She laughed scornfully.

"Is it yet to earn?"

"His blood be upon your head," he said sternly. "I will meet him." She laughed.

"I have no lover. The challenge is my own."

There was a quick murmur of laughter among the retainers, but their chief checked it with a glance.

"I am dull witted, lady; help my lack of brains."

She drew a deep breath.

"You sent a challenge to our clan, that one should contend with you. It was not an equal wager, yet there were those who would have died, had they not been overruled." Her eyes flashed.

"Also I took the risk," he reminded her.

"It was not an equal risk, as you knew." He frowned.

"Who shall deny his strength to the stronger man?" he asked.

"Shall he use it against a weaker?" she demanded. He frowned again.

"It is the way of these things."

"That he should take advantage against the weaker? Would he then use his strength against a woman?"

"No," said Macdonald, heartily. Surely not."

"Wherefore," said she, "I bring to you an equal challenge. She looked him in the eyes.

"If your challenge is such as a man may meet," he answered steadily, "I accept it unheard."

"It is an even risk," she said calmly. "Your life against mine."

"Never." She shrugged her shoulders.

"It is not my habit to fight a woman on any terms at all." She laughed scornfully.

"A woman is not so much to fear."

The gray-bearded Hector, who was reckoned wise, rested his trembling old hands on the table and leaned forward.

"A woman of all things is most to fear," he said.

"Before age has brought wisdom, do you fear?"

She turned haughtily to Alan.

"Aye," he said, "I greatly fear."

"The risk is only equal." He shook his head.

"A woman's life is more to a man than his own."

"My life is naught to you," she answered. He looked her in the face boldly.

"Try me, lady," he said; and the thought crossed her mind that Alan Macdonald had been good to have as a friend, but she bit her lip and answered coldly:

"Such as my life is, I dare risk it."

She put her hand in her bosom and drew out two quaint phials of colored glass, with stoppers of dull wrought gold.

"Will you drink a toast with me?" she asked.

"Surely," he answered, "if it is such as a man may." But he looked at the two strange vessels and liked them not.

"It is an innocent toast enough and harmless—if you drink the one."

"And if I drink the other?"

"It is only death."

"There are worse things," he told her. She pushed the phials smilingly toward him.

"Choose. I will drain the other."

"And then?"

"One of us will gain the valley, and the other will feel not loss."

He took up the phials and held them in the sunlight that streamed to the floor. Then he put them down again.

"I pray you send some other challenger," he begged.

"The challenge is mine," she insisted. "If you are no coward, choose now." He shook his head, and she rose from the chair. "I will go to my father

THE STAR OIL BURNER
ITS OWN GAS MAKER
(Patentees N. L. Rigby and S. S. Sprague)

This Burner is offered to the public upon its merits. It is not an experiment, but a practically tested and successful invention. It has no superior for safety, simplicity, economy and durability. It is made without bolts, screws or rivets. It makes a pure hydro-carbon gas from low grade distillate oils, and gives you a fire as bright as the stars. Free from soot and smoke.

FULL OF COMFORT AND PLEASURE

The California Limited Log-Book:

I have traveled over many railroads and have failed to find one equal to the "Santa Fe." Without doubt the California Limited is the most luxurious train in the world. The service is excellent in every respect, and the attentions and courtesy shown by the employes is most gentlemanly. A trip to California via the Santa Fe is one that should be long remembered; and it is full of both comfort and pleasure.

and tell him that Alan Macdonald was afraid."

The young chief flushed rosy red as a girl blushes.

"Send a man to tell me so," he cried fiercely.

"One less strong and less skilled in arms?" There was an angry sound among the men at their table, but he quieted it with a wave of his hand. "Come on," she tempted him. "Death is not so much to dread. Give me one, and I will drink first."

He lifted the little vessels again and watched them sprakle against the sunbeams. It was awesome, he thought, that death should come in such a guise; and he was angry with himself, because he feared that he feared.

"Dare you not?" she asked tauntingly.

"Aye," he said. "I dare. Give me which you will."

The wise man moved as if he would speak, but stopped at the look in her eyes.

"I should give you death," she answered. "For I know." Alan Macdonald looked hard at her, and saw that truly she was passing fair.

"Give me death if you will."

The wise man leaned forward again and again he said naught.

"I take no odds," she said. "Neither would I have the death of so generous a foe on my soul. For your honor, Alan Macdonald, choose."

He bowed and looked at the phials once more. One was green and one was pink, and either flashed in the sun.

"It were better to share one," he said.

"Aye," muttered the sage, "woman and man were made to live together."

"When they are foes," said Mary McAllister, "one is better dead."

"See that the lady is escorted home with all honor," he commanded, " if I die;" and before anyone could stay him he had drained the green phial. "Your health, madame."

Mary McAllister rose steadily, and put out her hand for the pink vessel.

"Your health, sir," she said. "You have won."

He saw that her color faded somewhat, her hand trembled somewhat and her bosom heaved as she raised death to her lips, and suddenly he dashed the vessel from her hand on to the floor, and shivered it into fragments.

"I pray you live," he begged, "and have me at your command."

Mary McAllister sank in her chair and buried her face in her hands for nearly a minute by the great clock that ticked on, as if life and death were nothing at all. When she looked up she was ashy pale, and she accepted her foeman's arm to rise.

"You are a very brave man, Alan Macdonald," she told him, in a slow, hushed voice. "Suffer me to go."

So he led her to the gateway in silence, and held her foot when she mounted.

"Friend or foe?" he asked under his breath. She looked at him with her great blue eyes.

"Foe," she whispered hoarsely, "but I honor you greatly."

Then she rode away into the mist that hung over the valley below, and he gazed after her till she was lost to view.

"There was never her like in all Scotland," he vowed. "She would have drunk her death."

"Aye," said the sage, "she would have taken it—and perchance she has more of it at home!"

The young chief stared at him for a moment, and then gave a great shout.

"My horse! Bring my horse!"

He ran to meet them as they came, leaped on his great black charger and rode down into the mist as if his senses were not in him.

"If harm should come to her!" he muttered. "Good God, if harm should come to her!"

He stroked his horse's mane and called it by every pet name to make it gallop faster. They rushed on, over hedges and ditches, and gray stone walls that grew suddenly out of the fog. He peered through the gloom with his eyes burning like fire, and saw nothing. Only as he rode up Mount Lonnon and the mist lifted a little, he caught a glimpse of someone riding far above and knew that he could never catch her by the way that she went. He drew a long breath and turned his horse aside from the track.

"A woman's life is worth more than a man's," he said, under his breath.

From the foot of the mountain to the castle high above the bridle path runs a long way round; and between bend and bend lies a great ravine that neither man nor beast had crossed, twenty feet at the narrowest from side to side. The edges overhang so that the bottom is not seen and when a stone falls one grows tired of listening for the distant crash below. Alan Macdonald rode straight for the ravine. When he came to the edge he looked till he found a plat of level grass, and there he rested his horse for a moment, and patted his neck and whispered in his ear.

"Now, boy, now!" he cried. The horse sprang forward over the even ground, gathered himself together on the edge of the abyss and flew into the air.

"Live together, or die together," said Alan Macdonald under his breath.

Then he saw his horse falling short of the black rock—felt him strike against it—was hurled forward with a crash—clutched at something hanging from above, and held dizzily to it—caught the sound of a woman's cry—clung mechanically to something, he did not know what—heard a dull thud. That must be his horse fallen below—he would follow in a moment—his hand seemed unclosing—he was going, going—Then he remembered no more for a time.

When he found the world again he was lying in some long grass, he thought, and there was something yet softer under his head. He could see nothing at first but the mist and the swaying tops of the trees. He was not sure whether he was dead or alive till he tried to stir and groaned for the pain. Then a woman's face hung over him, framed in the mist—the face of Mary McAllister.

"I thought," he said in a faint voice, unlike his own, "I thought I was dead." He lost the face again and heard no answer. "Perhaps," he muttered, "I am." He tried to raise himself and barely stifled another groan.

"You must not move," said a very gentle voice, "you are badly hurt, very badly, I fear."

"Yes." He tried to look around at her.

"Only be still,," she entreated. "I have sent for men to carry you. They will come soon."

"Soon," he muttered. Then he began to wander in his mind, and clutched at the air, dreaming that he was hanging over the ravine, but he found two soft hands holding his arms.

"You are not there now," she assured him. "You are safe, quite safe." He roused again.

"How—did it—happen?"

"You were hanging by a dead branch. "I—I lifted you here."

"I owe my life to you," He smiled as if the thought pleased him. "My foe."

"I do not think," she whispered, "we are foes any more. You must not move."

"You saved my life."

"You had saved mine."

"You were going to take the poison at home?"

She shivered, and suddenly he knew that his head was upon her lap. "Let me see your face again," he entreated, "in case I should die."

"You shall not die," she vowed passionately, and bent over him and let him see her face; and the tears were running down it, and one fell on his cheek.

"The poison?" he asked. "You would not have taken it?"

"Yes," she said, "I would."

"You will not now? For the love of Heaven, dear lady?"

"Why did you take the leap?"

He smiled faintly. "For you."

She looked right into his eyes.

"Why do you care so much for my life?"

Because he was dazen, the fine speeches he tried to fashion would not shape themselves to an end. So he said simply, "I love you."

"Then," she said, "since you won my life, keep it, and do with it as you will;" and he trurned to look at her without a moan at the pain.

"If I rise a whole man," he said, "I will give you my whole heart.' She looked at him with a glitter in her eyes.

"And if you do not," she said, "I will take it."

And because he was so helpless and his eyes pleaded with her so, she bent down her head and let him kiss her red lips.

"To live or die together," she vowed.

So when the leech came with his herbs and bandages, she whispered to him to use all his skill.

"For," she said, "you hold two lives in your hands."

Some said it was the leech's craft that saved him, and some said it was the gentle nursing of Mary McAllister, and some said it was his own great strength, and some said it was the strength of his love for her; but Hector, who was old and wise, put it all to the mercy of God. And when Alan Macdonald was recovered the clans went down from the mountains, with white favors in their bonnets, and married them in the valley between.—Leslie's Monthly.

SIMPLE BREAKFAST.

We serve simple breakfasts because we believe it to be poor policy to start the day with a stomach overloaded with heavy foods, also because we believe that the time, money and force spent in the preparation of rich, indigestible meals is worse than wasted. Scientists and chemists have proved that a proper combination of fruits, cereals, eggs and milk form a perfectly balanced ration. These enter largely in our breakfasts, are easily prepared, and as our family is composed of brain-workers and students, are sufficiently sustaining. Here are a few samples taken from the past week:

Coffee, peaches, graham mush, omelet, white bread.

Cocoa, melons, egg on toast, graham bread.

Coffee, a ready-prepared cereal, dried beef with gravy on toast, prunes.

Cocoa, baked apples and cream, egg souffle, whole-wheat bread.

Coffee, muskmelons, hot corn bread and honey.

Hot breads, hot cakes, waffles, ham and fried foods of all sorts are eliminated. Thousands of people keep their energies at a low ebb while their stomachs are wrestling with these abominations.—Woman's Home Companion.

FEMINITIES.

If you won't lend, don't borrow.

The finest thing in any home—good humor.

Working with a leaky gasoline stove is courting death.

There is a difference between being friendly and being familiar.

Some day children will be fed and reared as carefully as live stock.

Recipe for a stew: A trifle of fret, a pinch of regret, a cross word or two.

An M. D. says dyspeptics would not "chew the rag" so much if they chewed their victuals more.

EXPERIMENTS WITH INOCULATION.

(Continued from First Page.)

and had nodules, but the same was true of plants which received no manure. That manure may favor the development of alfalfa bacteria when they are already in the soil may possibly be true, but I do not think it furnishes them unless it is made from alfalfa hay or the hay of nearly related plants in the "Medicago" family, for alfalfa's botanical name is Medicago Sativa.

* * *

Whether the quality of alfalfa is improved by having an abundance of bacteria is a question on which there is no direct evidence which has come to my notice, but there is some indirect evidence which favors an affirmative answer.

In an experiment conducted at the Michigan experiment station, in which one plot of cowpeas was inoculated and another was not, it was found that the peas from the inoculated plot had nearly one-half more crude bacteria than peas from the other plot; hence, were more valuable for feeding purposes. If this is true of cowpeas it is probably true of alfalfa also, and it raises the question whether an advantage may not come from artificial inoculation even where land is slightly inoculated to start with.

I hope farmers will try inoculation wherever they sow alfalfa or at least a part of the field, and thus demonstrate for themselves whether their crop is benefited by it."

Every dairyman, whether he keeps 5 cows or 50, should grow a succession of succulent foods for the cows. It can be done in California.

Cocoanut Meal	1.55

San Francisco Markets.

San Francisco, October 4, 1905.

Dairy.

Again butter has advanced a cent a pound in some classes, but the demand is very quiet and there is not much life in the market; most buyers are pursuing a hand to mouth policy in placing orders. As a rule, the better offerings command top quotations, but the lower grades are often shaded.

BUTTER—Per lb:	
Creamery, fancy	.27 @28
Do, good to choice	.26@27
Dairy, choice	.24@26
California Storage	.23 @25
Eastern Creamery	.22½@24
Eastern ladle	.20 @21

CHEESE—Per lb:	
California Creamery, mild, new, extra	.13 @14
Do, choice	.11 @12
Young America	.13 @14
Eastern	.15 @17

Eggs.

Strictly fancy ranch eggs are very scarce and quickly picked up at top quotations. There has been a general advance during the week. Notwithstanding this, the greater number of buyers show a preference for storage grades, which command full quotations.

EGGS—Per doz:	
Ranch, good to fancy	.36 @39
Ranch, selected large	.40 @41
California storage	25 @28
Eastern, extra	.27@27½
Eastern, firsts	.24@26
Eastern, seconds	.21@23

Poultry.

POULTRY—Old Roosters, per doz., $4.50@5; young Roosters, $4.50@5.50 Fryers, $3.50@4; Broilers, 3½@4½. Hens, small, $4.50@5; large, $6@7; Live Turkeys, per lb., 21@23c; Spring Turkeys, 24@25c; Ducks, old, $4.50@$5.50; young, $4.50@6; Geese, per pair, $2; Goslings, $2.25@2.50; Pigeons, per doz., old, $1.25@1.50; young Pigeons, $2@2.25.

Fresh Fruits.

DECIDUOUS FRUITS—Apples, per box, fancy, 90@$1.25; common to choice, 40@75c.

Figs, per box, Black, 40@85c, as to size of package.

Pears, per box, Bartlett, $1.50@2; Winter Nellis, 75@$1.25; other varieties, per box, 40@$1.

Peaches, per small box, 75c@$1; carrier, 75c@$1.

Table Grapes—Per box or crate: Seedless, $1@1.10; Muscats, 50@85c; Cornichon, 75@90c; Blacks, 40@65c, Tokays, 65@90c; Isabellas, 85c@$1; open boxes, 75c@$1.50, as to variety.

Wine grapes—Per ton. Zinfandel, $24@30; Mission, $20@24; White, $18@22.

Pomegranates—Per box, 65c@$1.50.

Plums—Per box or crate, 40@75c.

Prunes—Per box or crate, $1@1.50.

Quinces—Per box, 65@75c.

MELONS—Cantaloupes—Per crate, $1@1.50.

Watermelons, per doz, $1.50@4; Nutmeg Melons, per box, 40@75c.

BERRIES—Blackberries—Per chest, $3@4.

Raspberries—Per chest, $3.50@6.

Strawberries—Per chest, Long worths, $4@6; large varieties, $3.50@5; Santa Clara, $4@6.

Huckleberries—Per lb., 5@8c.

Cranberries—Cape Cod per bbl, $8.50@9.50; Oregon, per box, $3@3.25.

Citrus Fruits.

Citrus Fruits—Per box: Oranges, Valencias, $1.50@4; Lemons, $4@4.50; Limes, $4@4.50; Grape Fruit, per box, $2@3.

Vegetables.

VEGETABLES—Tomatoes, per box, 25@65c; Green Peppers, per box, Chile 25@50c; do, Bell, 25@50c; Okra, per box, 35@50c; Beans, per lb, green 2@2½c; do, Wax, 3@4c; Lima, 1½@2½c; Garden Peas, per lb., 3@4c; Cucumbers, per box, 50@75c; Summer Squash, per box, 65c@$1; Egg Plant, per box, 35@50c; Garlic, per lb., 5@5½c; Green Corn, per sk, 50@$1, per crate, 75c@$1.25; Marrowfat Squash per ton, $10@15.

POTATOES—Per ctl: River Bur-

banks, 50@70c; Salinas Burbanks, 75c @$1.15; Early Rose, nominal; Garnet Chile, nominal; Sweet Potatoes, Merced, $1.40@1.55.

ONIONS—Per sk, Yellow, 60@75c.

Dried Fruits.

DRIED FRUITS—Prices for carload lots, f. o. b. at California common shipping points, in bags, are per lb, as follows:

Apples—Evaporated, fancy, 7¾@8c; choice, 7¼@7½c; standard, 6½@6¾c; Sun Dried, nominal.

Peaches—Crawford, fancy, 9c; choice, 8¼@8½c; standard, 8c; Muirs, fancy, 9½@10c; choice, 8½@9c; standard, 8¼c.

Prunes—Sack basis, f. o. b. For boxed goods add ¼@½c; four-size basis, 3½@4¼c; old crop, 2¾@3½c.

Pears—Bartlett, unpeeled halves, fancy, 12c; choice, 9@10c; standard, 7½@8c.

Apricots—Royal, fancy, 9½@10c; choice, 7¾@8½c; standard, 7¼c; Moorpark, fancy, 12c; choice, 8½@10c.

Figs—Per lb., White, 10-lb. bxs, fancy, 60c; choice, 55c; standard, 50c; Layers, 50@65c; bulk, fancy, 4c; choice, 3¼c; standard, 2¾c; ungraded, 3½c.

RAISINS—Prices per lb, f o b Fresno, are as follows: Bleached Thompsons, Seedless, extra fancy, 10½c; fancy, 9c; choice, 8c; standard, 7c; Bleached Sultanas, fancy, 7c; choice, 6c; standard, 5½c. Prices are for 50-lb cases, f. o. b. discount of 1½ per cent for cash.

Honey and Beeswax.

HONEY—New crop, Comb, per lb., 10@12c; Extracted Water White, 6c; Light Amber, 5@5½c; Dark Amber, 3@4c; Hawaiian, 2@2½c.

BEESWAX—Per lb, 26@28c.

Hops.

The price of desirable old crop is nominal at 12@14c per lb., according to quality.

Beans and Seeds.

BEANS—Prices per ctl for choice selections of new crop stock: Large White, $2.25@2.40; small do, $3@3.25; Pea, nominal; Limas, $3.60@3.85; common shipping points, $3.25@3.50; Red, $3@3.50; Pink, $2@2.35; Bayos, $2.75@3.25; Blackeyes, $3.75@4.25; Red Kidneys, $3.50@3.75; Horse Beans, $1.25@1.75.

DRIED PEAS—Prices per ctl: Niles, $2@$2.25; Green $2.25@2.50; Field, $1.75@2.25.

Live Stock.

CATTLE—No. 1 Steers, 6½@6¾c; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers, 5½c; second quality, 4½@5c; third quality, 4c; thin Cows and Heifers, 3@4c, Bulls and Stags, 2@3½c. Prices for all descriptions less 50 per cent for shrinkage.

CALVES—Light, per lb, 4¼@4¾c, gross weight; medium, 3¾@4c; heavy, 3½c gross weight.

SHEEP—Per lb: Wethers, No. 1, 3¾@4¼c, gross weight; Ewes, No. 1, 3¼@3¾c, gross weight.

LAMBS—Suckling, $2.75@3.25 per head or 4½@5c per lb., live weight.

HOGS—Per lb.: Hard grain fed, weighing alive 80 to 130 lbs., 5¼c; 130 to 250 lbs, 5½c; 250 to 350 lbs., 5¼c; rough heavy, 4@4¼c; common, 3½@4c.

Hay and Feedstuffs.

HAY—Per ton: Wheat, $10@15.50; Wheat and Oat, $10@14; Oat, $8@12; Barley, $8@11; Clover, $7@10; Alfalfa, $6@9; Stock, $5@6.

FEED CORN MEAL—Choice grades, per ton, $30@30.50.

STRAW—Good to choice, per bale, 30@50c.

FEED—Mixed Feed, per ton, $23@24; Calfalfa Meal, per ton, $22.50; in carload lots, $21; Mealfalfa, per ton, $20; in carload lots, $18.

BRAN—Per ton, $23@24.

CRACKED CORN—Choice stock, per ton, $30.50@31.

OILCAKE MEAL—In lots of 20 tons, $33.50 per ton; 10 tons, $34; 5 tons, $34.50; less quantity, $35. Prices are mill rates and are subject to change without notice.

MIDDLINGS—Per ton, $26.50@29.50.

GROUND BARLEY—Per ton, $22.50@23.50.

OATS—Good to choice White $1.37½@1,45; Red, $1.35@1.50 for choice to fancy; $1.15@1.32½ for common to fair; Black for seed, $1.60@1.75; lower grades, $1.25@1.55.

RYE—Good to choice, per ctl, nominal; new, $1.45@1.52½.

CORN—Good to choice, per ctl: California, new, large, Yellow, $1.45@1.50; small do, $1.60@1.65; White, $1.40@1.45; Eastern Yellow, $1.40@1.42½; White, $1.40@1.42½; mixed, $1.35@1.40.

CITRUS MARKETS

Lemons and Valencias are the only stocks going forward and both command fair prices in the Eastern centers when the fruit is good, but this is not always the case, some lots showing much decay.

New York.

Two cars of California fruit went at auction Friday, one each of lemons and Valencias. The latter were good and ranged from $5.25 to $5.95, while the lemons brought as high as $4.45 per box.

Five cars of lemons and Valencias were offered Tuesday, bringing $5.10@$5.80 for the oranges and $4.25@$5.45 for lemons.

The market was strong on Valencias Wednesday. Six cars were offered and brought from $3.30 to $7.90, as to grade. Lemons ranged from $3.45 to $5.45.

Boston.

Five cars were auctioned Monday, consisting of lemons and Valencias. The market was strong on Valencias and weaker on lemons, Valencias, $3.20@$4.75; lemons, $3.10@$4.65.

Only one car of lemons was offered Tuesday. They were fancy and brought $3.75 per box. Wednesday's offerings were one car each of Valencias and lemons. The Valencias were choice and averaged $3.75 per box, while lemons were steady at $4.50@$5.20.

Philadelphia.

One car of lemons and one of Valencias were offered Monday. The latter was poor stock and brought $3.00, while the lemons, high grade, brought $4.85@5.55.

Two cars were sold Tuesday, lemons bringing $4.70@$5.25, and Valencias ranging from $3.25 to $4.60.

Citrus Shipments.

Total shipments of citrus fruit to date are 29,334 cars, of which 4251 cars were lemons.

Too late for publication this week was received a lengthy notice of the important meeting of the State Commission to select a site for the State Pathological Laboratory and Experiment Station. The meeting has been called by Gov. Pardee to meet at 1:30 p. m., Thursday, October 12th, in the assembly room of the Chamber of Commerce at Los Angeles. The location is confined to one of the seven southern counties and all individuals and communities interested are invited to present their suggestions through the secretary of the commission, Victor H. Henderson, Berkeley, Calif. It is presumed that every one interested, who can be present at the meeting in Los Angeles, will be on hand at the time and place mentioned.

HIGHER PRICES FOR ORANGE TREES.

Inquiry develops the fact that the enormous supply of nursery orange trees has been greatly reduced during the past few years of low prices and that this year strictly high grade trees will probably command higher prices than for several years. This will be true especially of Valencias, for which a heavy demand is anticipated. Of navels there is a greater supply but with fair demand even they will certainly command more than last year.

We heard recently of one orchardist who had already placed his order for 22,000 trees. From this and other orders we take it the wise buyer is already selecting his trees.

At a meeting of the State Board of Public Works, held at Sacramento Saturday, it was decided to commence work building dykes along Sherman Island to protect it from the overflow, the people owning the land to co-operate with the State and bearing half of the expense, which is estimated to be $12,000.

Manager Kyle, of the cannery at Visalia, announces that that company has put out one hundred and seventy-five cars of canned fruit this year, this amount being far in excess of what was anticipated at the beginning of the season. For several weeks past this company has been paying out $2600 weekly for local help.

BUSINESS HUMMING.

The Cultivator man dropped into the manufactory of the Stearns Gas Engine Works a few days ago and found hard work to get any attention from the busy people engaged in putting out the engines for pumping plants and other farm purposes. Mr. Stearns, Jr. with a helper was busily engaged in testing a big twenty-five horse power just ordered out of the shop and the senior member of the firm was busy looking over the setting up of a large number of smaller engines. The twenty-five horse power undergoing the test was destined for a large Oxnard bean thresher and the object of the test was to see whether she would come up to the full twenty-five horse power. It had only been in running for a short time and the brake was just beginning to "smoke" nicely when the writer arrived. When it was in full motion, watch in hand, Mr. Stearns soon began counting revolutions and watching the indicator on the brake. When he had finished and the attendant took up the same task and a few minutes figuring showed she indicated 25.96 horse power. This was a satisfaction and Mr. Stearns further informed us that when she had run part of a day and smoothed down the bearings, a much higher increase might possibly be made.

As to the orders for this California house, the shops are now way behind and pulling every effort to get out the engines ordered. Besides the Oxnard order, two big jobs at Burbank, one at Coachella and others were referred to. We remarked that the year must be a satisfactory one to the establishment and Mr. Stearns simply answered "best ever."

BURN AIR.

California is long on its supply of air and if it can be turned to good use for heating and cooking purposes, it will be money in the pockets of us all. The Hague Domestic Oil Burner people say that this is exactly what their burner does, uses far more air than it does oil. This burner is said to be one of the most effective and economical of oil burners and so simple in its making that there is absolutely nothing in it to get out of order. And as to its working, simply turn the crank, touch the match and the fire is on. It is so constructed that with the large inlet of air the combustion is perfect so that there is almost no soot deposited in the stovepipe or chimney. The advertisement for the burner appears in this week's Cultivator and to one who is interested in cheap fuel it should be interesting reading.

YARDS MATING UP.

The season for thoroughbred poultry has opened earlier this year than usual. J. T. Davis of Pomona informed us recently that he has already mated up some of his yards and as fast as possible filling orders in which he is already greatly behind. Mr. Davis' White Rocks are beauties and he regrets that last year's demand took too many of his eggs so that his supply of stock this year is lower than he wished. He has no pullets for sale but will dispose of a few choice cockerels.

From the Nitrate of Soda Propaganda, Wm. S. Myers, director, 12 John St., N. Y., has been received a handy little book, "The Globe Trotters' Dictionary," of which a limited edition has been printed and those of our readers who care to receive a copy will be furnished one, free, while they last. Address, as above, by letter and mention the Cultivator.

The American National Bank of San Francisco, under its present management, has made a wonderful growth since 1902; in March of that year having deposits of $387,728.70 and Sept. 15, 1905, three and a half years later, deposits of $5,066,660.78.

Wm. B. Dean of Los Angeles, manufacture of Dean's Pacific Incubator, has issued a very neat booklet covering the excellent points of his popular and successful incubator. From the testimonials of prominent and successful fanciers freely given we are led to believe it will pay any poultry raiser to write Mr. Dean for booklet, prices, etc.

AN IDEAL COUNTRY HIGHWAY.

The practice of planting roadsides with eucalypts or other suitable trees cannot be too highly commended. In winter they prove a protection from wind and rain; in summer they provide a cool, shady and pleasant drive, preventing the roadbed from drying out, thus reducing dust and sprinkling to a minimum; making oiled roads cooler and frequent re-oilings unnecessary. Added to this is a considerable fuel value obtainable once or twice in every decade.

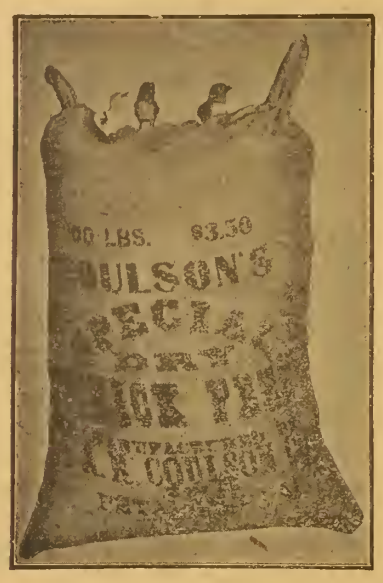
Coulson's Special Dry Chick Feed

FOR LITTLE CHICKS AND TURKEYS



You will have the best success you ever had in raising chickens if you will feed COULSON'S SPECIAL DRY CHICK FEED. Send for sample. It's good for turkeys as well.

This Chick Feed is composed of small pieces of cracked grains, also a variety of seeds and small pieces of charcoal, meat and bone. It therefore contains a variety of the best and most wholesome ingredients in the right proportions to promote the growth of chicks and turkeys and fully nourish them so they will reach maturity early, and be vigorous, strong, healthy birds.

ECONOMY IN USING COULSON'S SPECIAL CHICK FOOD.

By a series of tests it is found that chicks will gain weight much quicker on COULSON'S CHICK FOOD, and at less cost than those fed on grain.

Chicks fed on COULSON'S CHICK FOOD will reach the weight of two pounds a month sooner than those fed on grains, and they will reach the average weight of three pounds eight weeks sooner.

It is the knowledge acquired through patient study and keen observation which enables us to give the proper feed to poultry in order to raise the largest percentage of the chicks hatched. With COULSON'S SPECIAL DRY CHICK FOOD and COULSON'S GROWING CHICK FOOD many succeed in raising from 95 per cent to 98 per cent of the chicks hatched and you can do as well. TRY IT THIS YEAR.

Mr. Poultryman, there is only one way to buy, and that is, on record of what you want. If you want to raise lots of good chicks, buy good feed.

COPIES OF LETTERS RECEIVED.

I have fed your Chick Feed since I started this place about September 1st—last—and have sold 3,400 chicks and have 800 on hand now.

A. Mc HORTER.

I like your Special Chick Food better than anything I have ever used.

MRS. GEO. THISSELL, Jr.
Winters, Cal.

I have used your Special Chick Food since last March, and am still using it (July 7th). I believe it to be all right. I have lost less chicks than other years. It is good—the best I ever bought.

R. A. WHITFORD.

$500. What about?

I had read so much of your incubators that I thought I must try one, and I am more than pleased with the one I bought. I have also tried your Chick Food and think it fine. I have to go twenty-two miles to get it.

MRS. MAY LYMAN,
San Bernardino, Cal.

I have used your Special Dry Chick Food and recommend it to all my neighbors. MRS. IDA L. PARKER,
Eureka, Cal.

I think your Chick Feed is fine. I never lost one while I fed it, and never saw chicks grow so fast in my life.

MRS. HATTIE DEAN,
Mesa, Washington

BEGINNING LIFE ON COULSON'S CHICK FOOD.

TEN WEEKS OLD CHICKS RAISED ON COULSON'S CHICK FOOD.

Our chicks are doing splendidly on the Special Chick Food. No losses except by accident.

J. HUNTER.

COULSON'S FOOD GIVES BEST RESULTS.

I am a user of Coulson's Chick Food and have raised 1100 chicks this winter. The first hatch I used some other food and lost over sixty. My second I raised on COULSON'S CHICK FOOD, according to directions, and lost only 10. Then in my third hatch I fed COULSON'S CHICK FEED—dry—three times a day for three weeks, and out of 394 chicks, I lost only two, and all are doing fine. Now chicken raisers in this locality are wondering at my success, and I am praising COULSON'S FOOD as much as I know how.

(Signed) F. E. HEUSEL,
Half Moon Bay, Cal.

We receive much praise for this Special Chick Feed for it pleases the poultrymen and it pleases the chicks.

Many of the large poultry raisers near Petaluma purchase the Special Chick Food by the wagon load.

COULSON'S CHICK FOOD.

Contains ingredients that long experience in poultry raising has found best adapted to give nourishment to growing chicks. It is promptly digested; causes no indigestion; keeps bowels in normal condition. Chicks show increase in weight, strength and beauty when fed it exclusively. Little chicks need no other food for the first five or six weeks. Save your chicks and make good profits.

Keep them from bowel trouble and all ailments incident to the first five weeks. Profit lies in the chicks you raise to maturity—not in the number hatched. Give them a ration that makes healthy, well developed bodies.

Remember Mr. Bassett sold broilers only six weeks old for $3.75 a dozen. They were fed on Coulson's Chick Food

$500.00. Look for Little Envelope in 100 pound Sacks

CALIFORNIA CULTIVATOR

A WEEKLY JOURNAL DEVOTED TO AGRICULTURE IN ALL ITS BRANCHES.

Vol. XXV—No. 15 LOS ANGELES, CAL., FRIDAY, OCTOBER 13, 1905 Subscription $1 a Year

For Village and Country Improvement

By Major E. A. Routhe, Alhambra

One of the first things of consideration in civics is the standard of citizenship. First of all, this standard should be based upon intelligence and character. These qualifications taken together with the fact of being a freeholder, inspires an interest in public affairs, beyond that of the floating class. The freeholder is the permanent factor and should be more public spirited and should fel a greater concern in the affairs of the community than those who have no fixed place of abode. There is nothing that does more to promote the stability of good citizenship than the owning of the roof-tree that shelters the family; therefore, every good man should be induced and encouraged to secure a permanent holding. Permancy of location begets stability.

The secondary purpose, not less important, is to create and to cultivate a spirit of mutuality—a well-defined comity of interest. Next: to safeguard against mismanagement, imposition and corruption, to minimize the evils resulting from the operations of political parties, by freeing local questions from state and national issues and to aid in all works of reform and betterment. These things,however, do not necessitate a radical change in our traditional views of party work and responsibility. Efficiency and honesty should be the test-mark of the ones chosen for the conduct of public affairs. The operative life of a rural community, a village, town or city, should be conducted on broad lines for the promotion of health, comfort, morals and pleasure.

To do these things with liberality, without extravagance, is the problem that confronts us. In the things essential from the material standpoint, are good roadways, good sidewalks, good buildings of comely structure, good drainage, tree planting, public libraries, public baths, public drinking fountains for man and beast, public parks and plazas.

We have notable examples of good management in city and town government in many instance. Dresden affords perhaps the best illustration of municipal management in city life. Edinboro is the next. In those places the tenure of office is during good behavior and capability. Nothing intervenes in the life of the efficient official but sickness, death or misbehavior. Excepting in an office-seeking community or country, this system should certainly be regarded as satisfactory. Such a system eliminates these public places from politics, insures honesty and economy, and gives such dignity of character to the occupant of a public trust, as to place him beyond want and to assure him of the best social standing—a thing that is especially dear to the heart of every self-respecting man and his family.

The best instance of village govern ment, in this country is beyond question the town of Brookline, Massachuesetts. It is where Benjamin F. Baker was city clerk for 50 years. The present treasurer has had the custody of the public moneys for more than twenty years. The president of the local assembly of selectmen has occupied his place for 36 years.

A Rural Roadside.

Brookline has a simple form of government by direct legislation, in which the voice of every voter is heard. It is where the referendum principle is employed. It has proved practicable and satisfactory and by its use much friction and bitterness have been avoided. This village, as we call it, contains 20,000 souls and its record is free from "leaks," or any hint of graft-scandal.

A distinguished writer in commenting upon Brookline says that the standard of intelligence in that place is very high, and public spirit and pride in home government are quite pronounced. The best people are ever ready to give their time, thought and best energies to any work which public sentiment calls for, and to which the voters have given approval. These instances of urban management are cited as testimony in favor of simple methods in the matter of public service.

A good feature in the work of promotion is to have a committee of ten or more progressive, thoughtful and broad-minded persons, to act as a sort of advisory board to aid in friendly council the official legislative body, without undue interference, unless it is to engage in the innocent diversion of smashing municipal machines devised for the favored few; and from an ethical standpaint, to teach the graft of honesty.

The intelligent observance of the laws of hygiene is important. The best methods of drainage both by sewer and by well prepared surface drains, should be adopted. In the improvement of streets and alleys, means should be employed for the adoption of the best methods. The better that driveways and sidewalks are constructed, the more easily and cheaply will they be maintained. The establishment of alley-ways is a wise provision. By these, the delivery of all kinds of commodities for use and consumption is facilitated without disturbing travel upon the streets. They afford a place for poles with wires and for laying sewer mains. In Paris, Dresden and Edinboro, no one sees piles of packages and cases of merchandise upon the side-walk. All goods are taken in at the rear. Sidewalks are used exclusively for the use of pedestrians. Ambitious tradesmen cannot place their wares in the paths to show that they are still doing business at the old stand. Next to the improvement and care of the streets is the lighting and beautifying of them. A system of uniformity should be observed. An agreement or rule should be adopted, by which only one or two kinds of trees should be planted upon a street. Say, acacias upon one street, umbrella trees upon another, palms upon another, and so on. Vacant lots should be kept free from debris, and the burning of trash upon private premises should be prohibited. No one should consider that he had a right to fumigate an entire neighborhood after that style. Encouragement and assistance if necessary should be given to every occupant of a home, whether owned or hired, to beautify it with plants and flowers. Every public place should be likewise beautified, and with bits of art as well. Art is one of the flowers of civilization. Statues, arches and the towering peristyle should have their places in our parks. The stately and ornamental entrances to the finer residental places —such as may be seen at Los Angeles in Chester Place, St. James Park and Westmoreland Square, greatly enhance the beauty of a city; and would not be out of place in a village. There is so much to be said concerning this feature that it requires more than would be profitable on such an occasion as this. Provisions for a landscape gardener for a village community would be a good stroke of public economy. The tidiness, nicety of arrangement, the conversion of things of utility into things of beauty, all stand as indices of effective energy and refinement. We rise to a stature that dwarfs the old ideals. The effect of these rare pictures of still life is pleasingly impressive.

Reverting to the special subject of street improvements, the element of expense stands in the foreground for first consideration. The cost and maintenance expense are features which the tax payers view with apprehension bordering on alarm. The narrowing of the driveway space in residence districts is finding favor in many cities. A writer in the Portland Oregonian upon this subject, says that Minneapolis has recently been experimenting in this line and is pleased with the result. He says:

"The question of cost was calculated well before the change was made and it was discovered that the amount saved by paving 24 feet instead of 30 feet wide, assuming paving, curb and gutter to cost $2 per square yard, is $7,040 per mile. Every foot that the paving is narrowed saves $1,173 per

(Continued on Page 358)

California Horticulturally

By John Isaac, Sacramento, Cal.

A FUNGUS DEATH FOR GRASSHOPPERS.

An important discovery is reported from Los Banos, where a farmer discovered that grasshoppers were dying in great quantities, apparently from some fungous troubles. He gathered up a quantity of dead hoppers, ground up their bodies and mixed them with bran, which he fed to the living insects with fatal effect. This is an important discovery if true, and we would like to see it tried early in the season when the grasshoppers are a real pest. At the present time their season is over and they may be dying off from natural causes which the observer may have mistaken for some epidemic. A proper test should be made of the matter, however, and the diseased—and deceased grasshoppers should be carried over the winter months, the fungus which has attacked them be carefully cultivated until spring, and then its effects should be tried on the young and vigorous hoppers who have not yet grown tired of life and are ready to give up its burdens without extraneous assistance. The Agricultural Department at Washington carried on a series of experiments with fungous diseases for grasshoppers some years ago, but it was largely a failure, as the conditions where the great grasshopper invasions occur are unsuited for the fungus. Fungoids as a rule thrive best under moist conditions, the grasshopper does its best in arid conditions, and while the fungus was found to work all right under proper conditions of moisture it was a failure in the arid sections where the bulk of the grasshoppers were to be found. It was an easy matter to carry the fungus to the grasshoppers but when it was found necessary to remove the grasshoppers to a section where climatic conditions were suitable for the fungus to act, even Uncle Sam balked at the job.

* * *

A NEW STRINGFELLOW THEORY.

Mr. Stringfellow, the man who has acquired a great deal of notoriety in the East from what has been called his "method," a method which has been described as the cutting away of all the roots of a tree and then all the top and planting the label, is now out with a new theory, and that is, that orchards should not be cultivated. His idea is that tree holes should be dug in the wild sod, young trees with their tops and roots cut away be stuck in such holes and then left to yield big crops. We do not know how such a process would work in the sections where Mr. Stringfellow operates, but certainly in California nothing would be left but the dry sticks to mark the places where they had been set. We believe Mr. Stringfellow organized a company to plant an orchard after his plan in Texas. The result was a failure, but this was not on account of anything out of place in the theory, but was due to other unfortunate causes. The Stringfellow foolishness has not reached California, so we continue to prepare the soil carefully for our new orchards, and see that our young trees have some roots to support the tops. And after they are started we carefully attend to them and cultivate and irrigate and care for them just as long as we desire returns, and in spite of the peculiar Stringfellow theories we have found that it pays in results.

* * *

FRUIT GROWING PAYS.

The question is often raised whether fruit growing pays. This depends upon two things, the man and the land. Given both suitable, and the question may be answered in the affirmative. It has been so decided by J. Q. A. Ballou, of Santa Clara county, who states that from twenty acres of peaches this season he has disposed of 100 tons of fruit which netted him $47.50 per ton or $4,750 for his orchard, being $275.50 per acre. Fruit growing surely pays at such figures.

THE VALUE OF THE OLIVE.

In a recent letter to the Fresno Republican upon the food value of the olive, Frank Eberle, an excellent authority and a close observer, says:

"The food value of the olive is not yet fully appreciated by the people of America, but California, the great olive growing State, has started a crusade of education to teach the public how to use this wonderful fruit.

Both at the St. Louis Exposition last year, and at the Portland Exposition this year, California has been giving the world some useful information about the olive and other fruits that flourish in the Golden State. At the booth of a big California olive grower, in the Agricultural building at the Portland Exposition, ripe olives are given away to visitors, and many persons here see a ripe olive for the first time. At all California receptions at the exposition, and they are numerous, ripe olives are served to the guests. The State that grows the olive is teaching all America to eat the olive and to freely use the rich oil it produces.

Olive oil is one of the best vegetable fats, which in chemical composition, in nutritive value and use in the body, corresponds with the best corn-fed beef, without taxing the digestive organs as the latter does.

Olive oil is in a state of natural emulsion, ready to be digested promptly without the possibility of interfering with the digestion of any other food.

Pure olive oil is the perfect analogue of meat, and its value is beginning to be more generally recognized throughout the world. It has been observed that those who live upon olive oil as a common article of food are generally healthier and in much better condition than those who do not, because it contains more proteids and albumen than beefsteak. Two tablespoonfuls of pure olive oil contain more nourishment than one pound of meat or a cup of butter, without taxing the digestive organs.

The introduction of ripe olives to the market in America is of comparatively late date. The ripe olive as a very nourishing food has long been used by the Orientals. The Italian reserves his best ripe olives for home consumption, where they are a part of the daily diet, and are consumed in large quantities, taking the place of meat. Travelers in Palestine have been surprised at the power of endurance of their Bedouin guides, who live solely on ripe pickled olives, and hard, black bread, and endure the longest and hardest marches, apparently without effort or effect. In countries like Spain, Italy and Greece, the ripe olive is a staple article of food. Workmen toil hard all day on a ration of black bread and a handful of ripe, pickled olives, and keep in fine physical condition on this diet. All this may be taken as evidence of the highly nutritive qualities in the ripe olive.

In California, the ripe olives are prescribed in hospitals by physicians for the sick and convalescent. The oil blended with the salt in the pickle forms an appetizing digestor which stimulates secretion and builds up the appetite. Those who are posted never restrain their children from eating the ripe olives, knowing that they are more nourishing than meat, are easily digested and contain none of the dangerous heating qualities which accompany meat diet.

The imported green, or queen olive, is nothing more or less than an unripe, undeveloped and indigestible pickle. It is pickled and shipped from its native home in that state simply because it lends itself better to long transportation than the ripe olive. There is no nutrition in the green olive and physicians claim that when eaten in large quantities, especially by people with weak digestions, much harm is done by this indigestble, unripe article of food. The producers of these green olives know that the natives of Italy, France and Spain would not think of eating them, hence they are only put up for the foreign market as a commercial commodity. Americans must look to California for a healthy, palatable, sanitary article when they want a good olive. The food value of the green olive as compared with the ripe can be likened to that of a little, green apple to a rich, juicy, ripe one. According to olive experts, ripe olives and olive oil should not be considered as an occasional delicacy, but should form a part of the average diet and be considered a household necessity.

The demand for this commodity is constantly growing, which is a pleasing indication that the food value of the ripe olive is becoming better known and recognized, and doubtless the day will come when the green olive will be banished from the American table and the ripe California olive will be served in its place.

At the Lewis and Clark Exposition the olive is presented to the public in its most appetizing aspect, and California is doing a good work by seeking to introduce the ripe olive as a food for Americans."

CHARACTER OF BEES VARY.

There is a wonderful variety in the character of the bees in the different colonies even in the same apiary and of the same race. This difference shows itself in many ways, especially in the degree of excitability, energy and activity, and in the disposition to pass beyond the limits of the brood nest into a surplus apartment above. In selecting bees, no point is more important than that those should be chosen that enter willingly upon work in the supers. The Italian race or German race or crosses in which black blood predominates are superior. The most preferable of all is no doubt the Italian bees; they show great energy in gathering honey and are good in the defense of their hives against moth larvae and robber bees. They are more gentle than either the blacks or Cyprians and can be handled fairly well by the novice. They are quite prolific, handsome in color, having yellow bands, but must be well protected in order to winter well.

If you work for comb honey the problem of keeping down swarming with its consequent increase is a very difficult one. Large hives may do something toward it, but in spite of all you do the bees are likely to swarm. Perhaps the best way to do is to count on having the bees swarm once. Hive the swarm on the old stand, setting the old hive a little to one side to make place for it. In five or seven days remove the old hive to a new location, perhaps ten feet or more away, and the result of this removal will be that all the field bees from the old hive, when they return from gathering in the fields, instead of returning to the old hive, will go straight to the spot where it formerly stood and join the swarm. The swarm thus strengthened will give you the crop of honey and if the season is very good there may be some yield from the old colony, especially if there is a fall flow. If you want to get the most comb honey from your bees, hive the swarms on starters. Put only four frames in the new hive, with inch starters in them and a division board on each side, set the super from the parent hive, bees and all, into the new hive and hive your swarms into it. As they have nowhere else to put the honey it must of a necessity go up into the sections. The new hive should occupy the old stand so as to catch all the field bees which happened to be out at the time the swarm issued. In the course of three or four weeks the four frames will be occupied with brood, when the remaining space of the brood nest should be filled with frames of combs, or full sheets of foundation; if more starters are added too much drone comb will be built in them. By this method we have had a number of swarms fill and cap a super of twenty-eight sections, in two weeks and a half fill the second super. If the honey flow continues we count on a super every two weeks. Bees left to themselves will generally send out one swarm in a season, often sending out a second swarm, sometimes a third. In our own practice we always have supers partly full of empty comb and this makes the giving of room to the bees much more practicable than when empty sections are given, for there need be no delay in the work, no waiting on the builders, no hanging in clusters while the honey is waiting in the fields. The young bees then, do most of the comb building. Bees swarm because the circumstances do not suit them, they are ill at ease and lack sufficient room. If we do not wish them to swarm, we must give them sufficient room. A loose bottom board enables the beekeeper to raise the hive up whenever needed and to give as much space for ventilation as may be necessary. Drone rearing is a factor in swarming. In nearly every instance the colonies that swarm are those that have reared quite a large number of drones. A certain percentage of colonies will swarm in spite of anything that may be done. You must bear in mind that it takes but little to induce swarming during a good honey harvest. When moving bees during hot weather give them plenty of ventilation. The hive cover should be removed and a cover of wire gauze be placed on the hive. Better still, if the bees are to be moved any great distance, make a rim just the size of the hive and about two inches deep and tack the wire netting to this. The space between the top bars and the wire will give the bees a space to cluster and expel the heat and prevent the combs from melting down. Bees become very much excited and overheated when shut in and if possible should be moved at night. To make them still more comfortable, place on top of each hive a wet sponge and drive slowly. Our attention in the future should be given more to the practical management of bees, to reduce the labor and expense to the minimum and the more the work is simplfied, the more we shall feel that we are advancing. We believe that "mixed farming," so to speak, in the apiary will prevail in the near future. Better results are obtained from working for both comb and extracted honey and even a queenless nucleus can be made to care for extra queen cells. If the manipulation of bees shall be as much improved upon in the next half century as the general knowledge and appliances have for the same length of time in the past, we can but wonder what beekeepers will be doing fifty years hence.—Breeder.

The universe is not complete,
Without my work well done.
—Wm. C. Gannett.

BEES.

The bee and honey industry of this country is one that deserves to be encouraged.

It is held as an outcome of careful investigation that the flowers on hand could give employment to ten times as many honey bees as we possess.; though even as the matter stands the value of the products of the apiaries of the United States is put at between twenty and thirty million dollars.

All this is done with but little labor on the part of man, and no lessening of the value of the soil. We but direct the force, taking care that it is guarded from harm, and our reward is a large part of the returns.

These wonderful little beings of finely directed industry confer benefits not only as indicated, but it is further the fact that without them the amount of some of our best fruits would be seriously reduced.

It thus appears that in proportion as farmers and gardeners learn to make every edge cut the number of people engaged in the honey bee industry will increase. We should not merely lead every other nation in this respect, as is now our distinction, but the purpose ought to be to make full use of this particular good that is ours almost for the taking.

A reliable statement which we find made on the subject is that the greater part of our supply of extracted honey is from Arizona and California, and that New York, Pennsylvania and Vermont are in the foreground in looking after the comb article.—Farm and Home.

FEEDING.

Regarding feeding bees we note in an exchange:

The best food which can be supplied needy colonies is honey, of course. Where super frames are interchangeable with those in the hives, it is an easy matter to substitute full frames from the super for light ones in the hives. Another good way is to place supers containing unfinished and partially filled sections, over the hives. The bees will usually proceed at once to remove the honey from the sections, and deposit it in the combs below. Or they may be given extracted honey or sugar syrup by means of some good feeding apparatus, preferably honey, when it can be had that is absolutely free from foul brood contagion. But rather than risk honey about which nothing is known, I would feed sugar syrup. Bees will ordinarily winter well on sugar, especially if there is some honey to use with it, and if anything must be bought expressly for the purpose, sugar is probably quite a little cheaper.

IT'S PENNY WISE

Policy to set out a good tree, costing good money and then let the sun burn the bark, or the rabbits gnaw it when for $1.00 an acre you can get Yucca Tree Protectors that are practically indestructible. Write for free sample of the wrap. Yucca Mfg. Co., 2124 Willow St., Los Angeles.

"The Recollection of Quality Remains Long After the Price is Forgotten."
Trade Mark Registered.

"Old Friend Tools"

Every man feels a certain pleasure in the use of good tools. He knows that he can depend upon them to do their work and do it well. In time a man will become attached to a good tool as to an old friend, so in sympathy do they seem to become.

Keen Kutter Tools are the kind of tools that become old friends. They are the dependable, long-service kind.

There is neither economy or satisfaction in using poor tools, they are brittle and break easily, or they are soft and require constant sharpening, and they finally have to be discarded long before good tools would be worn out.

There is economy and satisfaction in buying Keen Kutter Tools because every Keen Kutter Tool is the best that brains, money and skill can produce.

Keen Kutter Tools have been the standard of America for 36 years and were awarded the Grand Prize at the St. Louis Exposition, the only prize of the kind ever given to a complete line of tools. The name Keen Kutter covers a complete line of tools so that you may buy any kind of tool with assurance of absolute satisfaction.

When, for instance, you buy a bit be sure to get one bearing the Keen Kutter name. Made in all leading patterns, highest quality of steel, finest finish and with long cutting lips, insuring long life.

Some of the other kinds of Keen Kutter Tools are: Axes, Adzes, Hammers, Hatchets, Chisels, Screw Drivers, Auger Bits, Files, Planes, Draw Knives, Saws, Tool Cabinets, Scythes, Hay Knives, Grass Hooks, Brush Hooks, Corn Knives, Eye Hoes, Trowels, Pruning Shears, Tinners' Snips, Scissors, Shears, Hair Clippers, Horse Shears, Razors, etc., and knives of all kinds.

If your dealer does not keep Keen Kutter Tools, write us and learn where to get them. Send for Tool Booklet.

DWARF APPLES AND PEARS.

Apples and pears are successfully grown on dwarf stocks, are desirable for a garden, and bring fruit the second year from planting. Apples are dwarfed on Paradise and Ducine stocks and we prefer the latter. Paradise roots are very susceptible to wooly aphis and the trees are very much dwarfed. Ducine makes a little larger tree. All kinds of apples do well on these as far as we know. Pears are dwarfed on quince, but there are but a limited number that seem to thrive as dwarfs. Among these are the Duchess D'Angouleme, Easter Beurre, Winter Nellis, Colonel Wilder and Patrick Barry.

Standard trees do well trained against a wall or the side of a building. We prefer large growing trees where there is wall space enough to accommodate them. They may be trained flat against the wall and thus occupy very little space, where they will produce a large amount of fruit. We would place them on the north or east sides in preference to south or west for the reason that the reflection of heat from the sides during the hottest time of the day might burn the trees or fruit.

HEALDSBURG PRUNES FOR GERMANY AND LONDON.

The fruit packing season has only commenced a few weeks ago and Sheriffs Brothers are inclined to feel good over their pack so far. Up to Friday a total of twenty-one cars have left their packing house here. The company are employing about fifty hands and on an average of a car a day is being turned out.

The shipments so far include ten cars to Germany and six cars to London, and the remaining five cars have been shipped to New York. Things are busy around their packing house just now and will be so for the next six weeks. Over sixty cars of twenty tons each will be forwarded before the close of the season.

The pay roll of the company is averaging over $500 a week, quite an item to the business interests of this place. Before the close of the season the company expect to pay out over $100,000 to the prune growers of this vicinity.—Enterprise.

A CALIFORNIA PRUNE GROWER IN LONDON.

Our prunes, I regret to say, are discredited. At the Army and Navy Junior Stores, Regent Street, London, where an immense business is done, I saw no prunes from California, and inquired why. The stores had ceased to buy them because they came to hand mouldy. "You do not mean sugared?" I inquired. "No, mouldy!" Visions of prunes, hot and steaming from the dip, jammed into boxes in the Santa Clara valley, as I have seen them, marveling, floated before my eyes.

"You may fool some of the people all the time, and all the people some of the time, but you can't fool all the people all the time." Packers, remember Abraham Lincoln when you pack.

It will ultimately serve your own interest, as well as that of your grower.—Edwin Berwick in Co-operative Journal.

COLORING OF FRUIT.

As well colored fruit sells to such an advantage it seems that growers should make an effort to supply the deficiency in soils where the fruit does not color well.

Men who have a knowledge of chemical fertilizers are the ones who are able to grow the best colored fruit. It has been the practice of some growers for years to use chemical fertilizers for the improvement of both color and quality of fruit, phosphoric acid and potash being largely used for the purpose. Where liberal quantities of potash are added to the soil, either the muriate or sulphate or the carbonate of potash obtained from wood ashes are exceedingly valuable as regards fruit coloring.

BORDEAUX FOR LEAF CURL.

"Complete success in crop saving on peach trees of the Elberta variety with the normal strength of spray attended applications on April 12. This was followed by the half strength formula May 17. Trees that were unsprayed retained no fruit and scarcely enough leaves to cast a shadow in June.

Two years later similar success was secured from one application of Bordeaux mixture made in April. A careful estimate showed that 85 per cent of unsprayed trees were diseased, while only 15 per cent of those sprayed showed effect of the leaf curl. The same effects were noted on other susceptible varieties of peach trees.

Many growers have duplicated these results, and we may rely upon the full efficiency of Bordeaux mixture in leaf curl prevention."

POLLENIZING CHERRIES.

The Chapman, a cross between the Bigarreau and Tartarian, seems to have a very beneficial effect on the Tartarians, which, since they are pollenized by adjacent trees bear much more heavily. In the same way it is noticed that the Tartarians which are adjacent to a Royal Anne seem to be more productive. In fact, some large Tartarian trees were shy bearers until they were pollenized by an adjacent Royal Anne cherry tree. Since then they have been heavy bearers every year. The effect of a tree in an adjacent orchard seems to be complete for about four trees. Beyond that it diminishes in proportion to distance. These are facts worthy of being noted by cherry orchardists, who used to have a certain crop every year, but have been suffering from light crops occasionally.

A curious instance of cherries ripening in midwinter is recorded by a Berkeley correspondent to the Country Gentleman: "During the third week in January there was a most extraordinary exhibition, at the headquarters of the Oakland Board of Trade, of ripe cherries, raspberries, loganberries, blackberries and a few clusters of large red currants.

These fruits were all picked from trees and bushes growing in Alameda county gardens, and matured and ripened in the open air. In several previous years ripe raspberries have been placed on exhibition at this season, but never before, even in California, have cherries ripened in midwinter.

The first cherries sent to the Oakland Board of Trade came from the home of Irving R. Whitney of Berkeley, and were gathered on the 11th of January. Other specimens were sent in later from various private gardens and ranches throughout Alameda County. From a ranch at Fruitvale, crabapples as well as cherries were sent.

The early fall rains, followed by an unprecedented season of warmth, even for this State are responsible for this topsy-turvy state of things. The Sacramento Valley, early in November was white with cherry, plum and pear blossoms, and old fruit growers shook their heads dolorously and predicted scant crops for the coming spring. At the present writing, however, there is no cause for alarm, as almonds, cherries and plums are blossoming profusely.

A GOPHER TRAP THAT KILLS. It's mighty discouraging to buy gopher traps that permit the gopher to escape after the trap has sprung. If you have used other traps you know that gophers crawl or are thrown out of them and the gopher that has been caught and got away will never be caught again. If you would take no chances with traps, you should investigate the merits of the

IMPROVED C. V. 2-RING GOPHER TRAP.

This is a patented trap, embodying all the latest improvements. It is superior to the Single ring, as well as the Clutch and Claw Traps, for the double ring disables the gopher and holds it securely, allowing no possibility of escape.

See that you get the genuine Improved C.V. 2-Ring. Sold everywhere for 25c; or if your dealer does not have them, send us his name and 25c. for sample trap or $2.50 for a dozen, which we will forward postpaid. FALLS MFG. CO., 14 Drumm St., San Francisco.

CITRUS FRUITS

By C. A. Day. Pasadena

GUM DISEASE.

Of late complaints have come from a number of citrus fruit growers of Los Angeles County of the prevalence of the gum disease in citrus trees. Some months ago this subject was discussed in the columns of the Cultivator and information given as to the nature of the disease and the remedies to apply, but for the reason that many of the readers of an agricultural journal fail to file away the back numbers, it becomes necessary to reprint valuable information when it is timely. I have had no experience with this disease in my orchard but have had my attention called to cases in my district. From published accounts it would seem that the most serious form of this disease (root-rot) is more prevalent in Florida than in California, and yet many cases of the root-rot have developed in orange orchards of Southern California.

* * *

Nature of Disease.—It is confined to the crown and main roots of the tree extending a foot or so above the ground and downward along the roots. Above the ground there is an exundation of the sap, which breaks through the bark and congeals in the form of a gum. Under the bark of the diseased portion is found a yellow sticky fluid. The disease destroys the larger roots and gradually works around the crown of the tree, girdling and eventually killing it. In many cases the tree is kept alive for some time by a narrow strip of live bark connecting a few small live roots with the top. It might be well to say in this connection that the best treatment for a badly diseased orchard is to take the trees out and replace with young, healthy stock.

The disease is said to be of a bacterial nature and infectious where conditions are favorable for its development.

* * *

Conditions favorable for the development of the disease.— As given by a Florida writer, these are as follows: Deep setting, wet soggy soil, the use of rank organic fertilizer, planting in localities underlaid with hard pan, faulty drainage, a shaded condition of the soil. Moist, damp conditions of soil are produced about the tree which in warm citrus climates is exactly suited to the development of the disease. In one case here in Los Angeles County, where the disease suddenly developed, the owner thought it due to a heavy cover crop that with unusual and continuous rains gave a moist condition around the trees. This would seem to correspond with the theory of the Florida writer. In another case an orchard irrigated by the basin system did not develop the disease until a change from the basin to the furrow system, and it then appeared on both heavy and light soils.

In the orchard irrigated by the basin system there had developed a mass of fibrous roots where the basin was made for irrigating. With the change from basin to furrow system, the sedimentary soil of the old basin immediately around the tree became hard and compact, shutting out the air from the base of the tree and the roots. It is well known that dry air is destructive to germs and the theory is advanced that the close, hard, sedimentary soil shut out the air and the germs of the disease present in the soil were under these conditions developed. There seems to be some good foundation for this theory from the fact that the removal of the soil from around the crown of a diseased tree in a measure checks the disease, even where no other remedies are applied.

In one instance an orchardist discovering the disease in the first stages, removed the soil for some depth from around the trees with the immediate effect of checking the advance of the disease.

If the disease is a form of vegetable parasite of the fungous or bacterial order it is easy to account for its rapid growth and development under conditions of warmth and moisture, and this would fit the theory of defective drainage, soggy conditions of soil, too much shade, a compact condition of the soil around the base and over the root system. In one case of gum disease that came to my notice, a group of orange trees in a slight depression at the outskirts of the orchard were diseased, and individual trees across the street were also attacked. The row of trees on the street were walnut and peach trees. I inspected one of the walnut trees thus affected and found the same diseased condition of the roots as on the orange trees. This seemed to prove that the disease under favorable conditions was infectuous and that the germs were in the soil and attacked the walnut and peach trees as well as the orange trees. The disease probably originated on the orange trees and spread to the others. The disease in this case did not spread beyond a small group of trees. Outside of this group the surrounding trees in the orchard were not affected.

In another orchard of heavy, close soil, a group of trees standing in a low place, where the irrigation water settled in considerable quantity, were affected with the disease, but on higher and adjoining ground the disease did not develop.

We have numerous instances on record where the disease developed at the lower end of the orchard where a surplus of irrigation water accumulated and probably a hard, close strata of sub-soil allowed but poor drainage. As to deeply set trees, we can readily see that with such proper conditions of soil and moisture, the disease would more readily develop than with a shallow set tree where the base and main roots would dry out much quicker than those of the deep-set tree. A superabundance of rank stable manure with a surplus of moisture might favor the development of the disease, as the effect of the stable manure is to conserve the moisture and prevent rapid exaporation.

* * *

Resistant stock.—It is claimed in Florida that the sour orange, rough lemon, trifoliate, and pomelo stocks are resistant and that the sweet orange and lemon stocks are subject to the disease.

The majority of the stock used to bud upon here in California consists of the sweet orange, and it may be due to that fact that the disease is as prevalent here, as it is; notwithstanding the conditions otherwise are not as favorable here as in Florida.

* * *

Remedy.—As in the case of pernicious insects I believe that prevention is the cheapest. I would avoid, if possible, basin irrigation directly around the trees, provide good drainage, and where the soil compacts immediately around the base of the tree and over the main root system, break it up, as dry air is unfavorable to the development of the germs. I would avoid applying stable manure close to the trunk of the trees. Where the disease is well advanced it would seem best to remove the tree and plant a strong, vigorous one in its place and remove the conditions favorable to the development of the disease.

Where the disease is not too far advanced, remove the soil from the base of the tree and uncover all roots that are diseased, cut out and remove all diseased bark and wood and scrape such parts clean, carefully gathering up and burning the scrapings.

With a brush paint the freshly cut wood with solutions 3, 4 or 5 or sprinkle No. 4 or 5 over the cut surface and adjoining soil.

Solution No. 3.—Unslacked lime 1 peck; crude carbolic acid 4 ounces; salt 3 pounds; water 2 gallons; Slack the lime in two gallons of water, then add the crude carbolic acid and stir in the salt; if too thick add a little water.

Solution No. 4.—Mix together crude carbolic acid and water, equal parts, by weight.

Caution and care must be used in applying carbolic acid as the strength of the commercial acid varies, and it must be diluted to such an extent that the vegetable tissues will not be destroyed by it.

Solution No. 5.—Mix together sulphuric acid and water in proportions of three of the former to seventeen of the latter.

It is sometimes necessary to treat more than once. Finally fill in with loose soil and sprinkle the surface with the solution.

DOING LOTS OF GOOD.

Warm? yes, extra warm for October, but just think how much good this weather is doing, both to deciduous and citrus fruit crops. Then sing praises, not mouth cuss words.—Citrograph.

BY ERNEST BRAUNTON, LOS ANGELES, CAL.

A SONG OF THE NORTH.

Set some trees upon the commons,
Ashes, linden, poplars, birch,
Set them out around the school house,
Plant them thick about the church,
Have the children's playground shaded,
And the public walks as well,
And the joys from these arising,
Coming ages glad will tell.

A HOME FOR SIX BITS.

How many residing on bare, shabby, shadeless farms know that a restful, shady farm home may be made by the small outlay of seventy-five cents. It costs just that much for a box of one hundred sturdy young blue gums and these planted along the windy side of the farm buildings and clustered around the house to form a background will make a complete transformation of the local landscape. Where all was bare and ugly will be clothed with beauty. Instead of the house plat being hot, dry and dusty, it will be cool and inviting. That inhospitable look so common to many farms will give way before the growing trees to one of cheerful hospitality. Children and animals heretofore forced to keep in the shade of the buildings will have a natural, cool retreat in which to rest or gambol. Neighbors and passersby will say: "How improved Smith's place looks of late." Some day a searcher for a home will ask the price of the farm with the remark that it looks homelike and restful. The disease will be catching and before long the community will take on an improved appearance and the ever attendant increasing value and importance. Another two or four bits will provide seeds to plant permanent beds of flowers around the house and in the yard. Those in new or unplanted sections cannot afford to let this matter pass unheeded for a single season. Six bits or a dollar makes the difference between a farm house and a country home. Which will you have?

ORNAMENT THE YARD.

To begin with, this requires a love of nature, some time, labor and outlay of money. There are too many men who have no taste for the ornamental. The refining influence of trees, shrubs and flowers does not appeal to any of their finer sensibilities or perhaps I should say they are lacking in appreciation of the beautiful. The mothers and daughters of the farm are, as a rule, admirers of nature, but if they are so unfortunate as to have male members of the household who are wholly out of sympathy with them, they can make but little headway in ornamentation. Many women make home brighter by a little flower garden in the yard, summer and winter, or by a few house plants and are grumbled at for "foolin' away their time on such trash." Everyone of these good women, in their humble way, are making the world happier and better. Having time and means and the disposition to do the work, the proper planting of the home grounds is no easy task. There are a few fundamental principles that should always be borne in mind. The space in front of a farm house should be of ample dimension and proportioned to the height of the house. No trees, shrubbery or anything else should obstruct the view from the house to the front fence. No planting should be done in straight lines, nor should any sharp angles be made. The same rule will apply to walks and drives. The planting should be done mainly on the borders, the larger trees and shrubs in the background and the smaller plants in front. Large growing trees should not be planted on small grounds, as they are too much out of proportion. A small, neat, compact tree is better suited to small grounds.

Some people fancy a particular kind, other people prefer another kind. As all varieties cannot be grown there should be a selection of those sorts which will give the most satisfaction, all things considered.

WENLAND'S SOLANUM.

Among our more tender climbers none is deservedly more popular than the large, robust lilac-flowering vine known as Solanum Wendlandii. Its native home, Costa Rica, embraces much variation of climate and temperature from mountain snows to tropic swamps, and this plant comes from the temperate upland districts. Like most vigorous climbers, to see it at its best it must have plenty of room and a rich, light soil with copious waterings during the period of active growth. Under such conditions it blooms magnificently, surpassing all other vines in the number and size of flower heads. It seems peculiarly at home in those parts of California nearly free from frosts and when in good health, under best conditions, it is the most showy and satisfying of any climber grown in this State.

OUR BIG TREE.

Nearly all Californians know the "Big Tree" in its mature form, either through personal inspection or the ever present photograph. Comparitively few, however, know it as a decorative garden plant. It is one of the most shapely evergreens, when in a young state, that the garden holds and none in cultivation have yet grown large enough to lose an iota of their youthful beauty. They need little care and in Central and Southern California they thrive much better than their near relative, the redwood. Our illustration shows a typical growth of ten years of most ordinary care.

RURAL PARKS.

In all surburban or rural districts, park attractions are now great factors and constantly growing features of the times. They are necessities, not luxuries, not for any class or privileged few, but are priceless possessions for all the people and the one place where neither social, financial, intellectual nor political distinctions give any one citizen rights, prerogatives or privileges over another.

Our Big Tree.

DON'T PRUNE EVERYTHING.

When doing the fall pruning do not make the mistake of pruning flowering shrubs, such as deutzias, lilacs, syringas (Philadelphus), etc., for these should only be pruned immediately after flowering. Next spring they will flower from the wood made this summer and if this is cut away you will get a very light crop of blooms. Don't prune Bougainvilleas and tender vines, for if a hot spell comes afterward, a tender new growth will be induced just when the frost will catch it. Prune in the spring before the season's growth begins.

Plant the bulb beds as early as possible and keep the soil well enriched.

In the Vegetable Garden

OCTOBER VEGETABLE CALENDAR.

During the month you will find all vegetable growers very busy sowing seeds. It is in order to plant the following during October: Beans, cabbages, cauliflower, carrot, lettuce, onions, parsnips. peas, radish and spinach (every month), and turnips.

You will find that it pays to work the ground over very thoroughly several times and get the soil in the best possible condition. Such treatment will save much labor through all the season and goes far toward ensuring a good crop. Some attention should be paid to rotation of crops—do not plant root crops in the same place for two successive seasons or head crops either. Aim to grow a crop above the ground one year and follow it with one beneath the surface.

WINTER VEGETABLES.

Summer vegetable will soon be out of season. Even the luscious watermelon or the rich muskmelon or canteloupe lose their desirable flavor when colder weather comes. The fresh tomato, however, for cooking, will be in favor as late as the frost keeps away. This is also a reminder that a few vines may be preserved until later in the season by a light covering if we should have an early and destructive frost. Very late in the season the growth and maturity of fruit is so slow as to make less of a point in favor of late grown fruit. In choice, warm, foothill locations, with sunny exposure, conditions are more favorable, especially for summer planted roots, which are more vigorous than those that have been bearing heavily for the whole season. This all reminds us that if we are to have a continuous supply of vegetables in season we must keep planting, and sowing seed. All of the commoner hardy vegetables will give a good supply for the table if sown at once in rich soil. Onions, turnips, corrots, peas, cabbage and the various salad and pot herbs for flavoring will give a good supply for the house during winter and spring and until they begin to run to seed, when the spring supply from sowing in early spring will furnish the table through all next summer. To grow the best rich soil and plenty of water are essential conditions and without them success will be only indifferent. With these factors an enjoyable meal is always at hand. In very favorable locations early potatoes may be still planted for family use, or if near a good market. A good quality of new potatoes may bring fancy prices along with green peas and other luscious vegetable for eastern tourists' use.

ONIONS GROWN UNDER MULCH.

Mulching tests for various vegetable have been made at the Nebraska experiment station, for two or three years past, and in most instances the mulch has proven beneficial enough to warrant it being practical for the busy farmer. Here are the results of the test of mulched onions last year: Twelve rows 100 feet long were planted in each of two plats side by side. These were started by sowing seed in boxes early in March and partially forced in the hot bed. They were then transplanted in the field plats in April or when the plant was four to six inches high. Two varieties were grown in each plat—Prize Taker and Red Wetherfield. Both plats were cultivated twice with wheel hoe and hand weeded once—just before the mulching, which was applied about June 10.

The work of placing the mulch (old wheat straw), on the plat just about balanced the work of cultivating and weeding the other plat for the balance of the season. Both plats are harvested in September and measures taken by weight. The heaviest yield was of mulched Prize Takers—579 bushels per acre. The per cent. of gains for the mulched plat over the cultivated plat was as follows: Prize Taker 12.4 per cent., Red Wetherfield 10.4 per cent. The onions were all of large, even size and sold on the Lincoln market at top prices—70 cents per bushel, wholesale. Last year being a wet season the gains of mulching were not as great as they would be in a dry season. Where material for mulch is easily obtained it will pay to use it in the onion bed.

GROW YOUR OWN VEGETABLES.

We have always contended that farmers in California make a serious mistake by not raising their own vegetables. Serious, not only from an economic, but from a sanitary standpoint. The number of nickles and dimes paid out annually for vegetables to "John" is surprising, or would be if any count were kept of it.

We'll wage a year's subscription that seventy-five per cent of our readers give John Chinaman every month more than enough to pay for the Cultivator a year.

And it's the meanest kind of way to spend money, too, for what you get for it isn't first-class by a long way, nor is it fresh or wholesome. Follow the Chinaman and see him wash off the bunches of lettuce or spinach in the irrigating ditch (sewer if he's near enough to a city) in order to keep the leaves in a half way fresh condition. Watch him rinse off the asparagus or salsify in the same way, and then stop and figure up if it wouldn't be nicer to say the least, to say nothing of cheaper, to raise your own "garden sass!"

Last week we drove from Whittier to La Habra and on the way noted a well kept vegetable garden that was a pleasure to look at. As we passed it we observed to our companion "That's the way to do things, and I'll warrant the house is equally up to date," and sure enough, the ranch house was in the very pink of condition; grounds neat, a well kept flower garden and nicely graveled walks. It didn't cost much—the vegetable garden paid for it all, we're sure—and it made life far more attractive to the occupants.

In several places we noted the same thing—a well kept vegetable garden was the adjunct to a well kept orchard and attractive home so, if Cultivator readers want to be up-to-date, raise your own vegetables.

Mother (reproachfully, to her small son)—Jamie, where have you been all afternoon?

Jamie (uneasily)—At Sunday school, mamma.

Mother—Then how is it you are wet and smell so of fish?

Jamie (in desperation)—Well, you see, I've been studying about Jonah and the whale, and—well—I guess it came off on my clothes.

Era of Prosperity Before Us.—According to the government crop reports for September, we are to experience a wonderful yield of our two staple crops for the Pacific Northwest and the Middle West. These portend a year of great national prosperity.

According to the calculations of the statistican of the New York Produce Exchange, the corn crop will reach 2,716,918,000 bushels—the largest total in our history, being nearly 200,000,000 bushels greater than the record breaking yield of 1902. In wheat the indicated yield is 704,447,000 bushels, a gain of 99,000,000 bushels over last year. Only once in our history has this record been surpassed, the famous 1901 crop, reaching a total of 748,460,218 bushels. Taking corn and wheat together, however, we have never had a more fruitful and roseate year.

The effect of this spurt in agricultural production on the general prosperity is obvious. To begin with, the marked increase in the wheat yield will greatly swell the volume of exports. From 1901 to 1904 our wheat crop steadily diminished in quantity. The total fell from 748,000,000 bushels in 1901 to 670,000,000 in 1902, 637,000,000 in 1903 and 605,000,000 in 1904. There were many experts who declared that our wheat area had been permanently decreased, the land being exhausted or turned to other uses. Wheat exports naturally fell off, and the theory was advanced that we were beginning to consume our own wheat crop and should never regain our lost position as a wheat exporter. In the fiscal year 1904-'05 our exports of grain fell to 43,700,000 bushels, although only so recently as 1902 we were exporting 234,000,000 bushels. Fortunately gains in manufactured exports more than made up for losses in raw materials, and we closed the year with the largest total we have ever reached in exports. But the bumper wheat crop of 1905, releasing at least 100,000,000 bushels additional for export, will help materially to carry our export trade for 1905-'06 to a new high level.

The Cultivator has maintained all along that the prosperity of the country for 1906 is assured. Of course, here in California, we are somewhat governed by climatic conditions for our local prosperity, but if we may rely on the weather bureau, at Washington, we can count on as much rain the coming season as we had last year. But we shall feel the effect of the general prosperity, however, no matter if we shall go short on rain—which we probably shall not—and our own products will be sufficient to give us a most prosperous season in 1906.

This year has been a phenomenal one for citrus growers; the prices they have received have been satisfactory in the extreme, and if we shall have another year of as good results, California will receive such an impetus from its own resources and in incoming population, as shall make us one of the most prosperous States in the Union.

In confirmation of this declaration, read what the New York Tribune says in reference to the returns we have had in this country from our cereal crops:

"To domestic trade the great crops now indicated will serve as an equally potent stimulus. Prosperity for the farmer means prosperity for the transporter, the middleman and the manufacturer. The railroads will find their business enlarged, and the wealth drawn from the soil will create a new demand along all lines of industry. The recent revival in the steel and iron trade is only one of the advance signs of a new wave of national prosperity—prosperity based not on fictitious booms or frenzied speculation, but on illimitable natural resources and genuine productive energy."

So we can have no reason to feel discouraged. The outlook is auspicious, we face the coming season with highest hopes and with the best of anticipations.

* * *

Affirms The Cultivator.—When yellow fever broke out in New Orleans, this paper called the attention to the necessity of cleaning up our coast towns to avoid any possibility of Southern California receiving a visit from this dread disease. It is a well-known fact that yellow fever, as well as typhoid follows uncleanly conditions, and is also carried by mosquitoes.

The State Board of Health has come out in a bulletin confirming the position taken by the Cultivator and urging city authorities to prevent the introduction of the disease by removing the causes which lead to it. Here is what the State Board of Health says in its bulletin: "The question is often asked if there is any danger of yelow fever in California. The answer to this must be that there is danger, although it is not great. Yellow fever is spread by a certain species of mosquito, and that mosquito has never been reported in California. If not here now, it might be brought in ships or cars, and so become naturalized, when we would soon have plenty of them. The mosquito is harmless unless it has bitten a person suffering with yellow fever, so should the mosquito develop here, no bad results would follow unless a case of yellow fever should be imported and the mosquito allowed to bite the patient. Our safety consists, first, in preventing the introduction of mosquitoes and destroying all their breeding-places; second, in keeping all cases or yellow fever protected from mosquitoes. Ships and cars from infected ports are fumigated to destroy the mosquitoes, and a close watch kept for any case of the fever. However, every health officer, physician and citizen has a duty to perform.

"We know the cause and can control it by united effort, and can take a valuable lesson from the intense suffering endured and great expense entailed by New Orleans during the past summer. The city was not properly sewered or drained, and had 70,000 cisterns all above ground, many of which were open and therefore breeding-places for mosquitoes. It has been an expensive fight, but one fought on scientific grounds, and science is winning out. Had all the citizens and physicians been prompt in reporting cases and accorded the health authorities an active support, the victory would have been more complete. The hiding of cases in this epidemic, as in all epidemics of contagious diseases everywhere, has been the cause of much of the suffering. Some time people will find that health authorities are working for their good."

* * *

Commendable Work.—The Grand Jury of Los Angeles County made a report last week to the Court, in which severe criticism is indulged in, on the condition of the public highways. It would seem that the sum of $250,000 is annually raised for our roads, that is, the taxpayers place that sum in the hands of the supervisors for road purposes, but the condition of the highways remains lamentably bad It was shown in the report of the Grand Jury that one supervisor in Los Angeles County has had a large fund at his disposal for over a year, and yet has done nothing to speak of in the way of repairs. What is the supervisor in the third district doing that he doesn't get to work? Very soon the wet season will fall upon us, the roads will be well nigh impossible from chuck holes and washes, and with heavy rains to come they will have to be abandoned. There are two bridges out on Vermont Avenue leading to Hollywood which have not been repaired this entire season. Who is to blame? No one but the supervisor in charge of that district unless the bridges are within the limit of the City of Los Angeles.

It would seem as if our road tax is large enough to insure keeping the highways in order. Such neglect of the people's rights demands explanation from some quarter.

If the supervisor in question is incompetent, he ought to resign and let some one take his place who will attend to the business of the district. The idea of allowing a road fund of $20,000 to remain in the treasury for a year, when the highways are needing every dollar of it in repairs, is little short of criminal carelessness. The people in the third district of Los Angeles County should call upon their supervisor to make good or step down and out.

The question of good roads in California is one of paramount importance. It is second only to the water question. We must have first class public highways or we can not improve in the county as we should. It is the business of the supervisors to look after the public highways and to see that the taxpayers get something for their money.

We are inclined to the view that the present law governing the making of public roads in California should be amended. Some highway commission ought to have them in charge and be responsible for them. Under the present law no one seems to exercise any interest in the welfare of the highways. It is time for the people to take the matter in hand.

* * *

The Teacher in the Rural Schools.—The time has come when our board of education ought to take the question out of door improvement into consideration in hiring teachers. One may travel all over the state without seeing many examples of improved school houses en route, and it comes to one's mind that in the education of the teacher nowadays there should be included a fairly comprehensive course on nature study and outdoor improvement. The adaptability of the young to nature's influences and teachings, and their enthusiastic love of garden work has been amply proved and is well realized, but leaders and instructors are positively necessary and these should be found in the teacher. And especially so in the rural schools. In the country, up to date, the missionary efforts of the Improvement League and Ladies' Auxiliaries have scarcely been heard of, and so the apathy characterizing the country in such a movement is very much in evidence, and will only be removed to an appreciable extent by the persistent activity of the school children with the intelligent cooperation of their teachers. In the country school teacher we should be able to find in due course the making of an apostle in outdoor improvement, whose influence through the children to the parents would be far-reaching, indeed. Unfortunately, the standard of education in the average teacher of the rural school is at present far from satisfactory, the normal schools, as a rule, not embodying in their curriculum such lines of study as would establish principles of taste and culture in the aspirants for the position of school teachers, and there must be some foundation in these directions to make their activity in outdoor improvement effective either in the school or country. Energy may be well directed towards making the country school teacher in fact as well as in thory an efficient disciple of the leaders in this great movement of the twentieth century.

* * *

Reinstated.—It is announced in Washington dispatches that the Secretary of Agriculture has determined to reinstate Dr. Moore because he has been vindicated by the Department of Justice after a full examination. Dr. Moore, it will be remembered, was discharged by Secretary Wilson because of his alleged official influence used to promote the sale of nitro-culture. As soon as the charges were made against him he resigned. It now appears as if he made a mistake to retire. Any man does, when under fire, unless he is guilty. Dr. Moore seems not to have been, hence, Mr. Wilson, desiring to do him justice, and to retain a valuable assistant, has decided to reinstate him.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

The vineyards of Sonoma County will yield but a little over half their usual crop.

The State Pathological Laboratory ought to be located either in, or close to, Redlands.—The Citrograph.

Grape prices around Cloverdale have advanced to $18—$20.50 per ton, a raise of $2.00 over last week's prices.

The raisin crops of Fresno Co., while short in quantity, is of unusually good quality. Wine grapes are an excellent crop.

The walnut crop around Saticoy is only about one-half the yield obtained last year, but the growers are persistent in claiming that the quality is much superior.

This year's experiments with pink beans by Tulare County farmers have demonstrated that at least $75 per acre can be cleared from the crop in ordinary years.

A melon growers association was organized at Imperial on Wednesday last and it is probable the onion growers may become members and cooperate with them.

The Pacific Coast Ginseng Company has organized at Mountain View, Santa Clara County. Ginseng and other medicinal plants will be propagated by the company .

The Pajaro valley will turn out more apples for export than last year, some authorities estimating the crop output from 2000 to 3000 cars. Already more than 1000 cars have gone out.

The grape crop in Cucamonga was badly damaged by blight this season. Hardly one-third of a crop was realized. The Italian Vineyard Co. sulphured their vines and got a good crop in consequence.

Grape picking is now under full sway. The crop is turning out better in some sections than was at first anticipated. The warm weather has been grand for the ripening and harvesting of the crop.

Highland orange growers are planting peas between the rows of trees, the vines to be plowed under later on and used for fertilizer. Necessity for this, during the past few years, has become more pronounced.

Over one-half the necessary acreage of sugar beets have been signed by the farmers around the new Tulare factory and no trouble is anticipated in getting a sufficient crop to ensure the factory's being employed at all times with a full force of hands.

E. E. Wilson of Orange received returns from New York last week on the sale of two carloads of late Valencia oranges, which beat all previous records for price. One carload sold for $2100.32 and the other for $2200.38. These figures will realize to the grower about $4 to $4.25 per box, on the trees.

The prune growers of Idaho are quite jubilant over the present condition of the market for their product and expect large profits on their crop. Just now the prices range from 75 cents to $1 a box where a short time ago 40 and 60 cents were offered. There seems to be a steady demand for all the prunes they have to sell.

Sixty carloads of Tokay grapes shipped from Sacramento and San Joaquin Counties through the California Fruit Exchange, from August 30 th to Sept. 29th, realized $96,546 in the Eastern markets. This was an average per car of 960 crates, of $1609.10. The maximum price received was $2255 for a carload, and $700 the minimum price.

The Board of Directors of the California Raisin Growers' Company has announced the following schedule of prices which it will ask for raisins this year, it was arranged on what is known as the 4 1-2 or sweatbox basis, and is as follows: Loose raisins, 4 crown, 6 1-2c per pound; 3 crown, 6c; two crown, 5 3-4c; seeded raisins, fancy, 12 oz., 6 5-8c; choice, 16 oz., 8 1-4c; fancy 12 oz., 6 5-8c; choice, 16 oz., 8c; choice, 12 oz., 63-8c.

Prof. S. M. Tracey of the United States department of agriculture and agent of the bureau of plant industry arrived in Los Angeles a few days ago. His purpose in coming to this section is to ascertain if it is possible to recommend to the citrus fruit growers some plant or grass crop that can be successfully grown between the orange and lemon trees and used as a fertilizer to take the place of the chemical fertilizers that are necessary for use each year.

AGRICULTURE.

The government now has over 700 two year old date palms growing near Mecca, in Riverside County.

Wheat in the Boise valley, Idaho, this year made an average of 35 to 55 bushels per acre, oats 40 to 104, and barley about 40.

The sugar beet crop around Compton is reported, in some instances, as running over 35 tons to the acre and as high as 22 per cent. in sugar.

The Santa Barbara bean crop is lighter than that of last year owing to the unusually rank growth of the vines. This has been caused in part by an excess of cloudy weather which has also induced mildew.

The Central California Agricultural Fair held at the fair grounds in Hanford, October 9-14 inclusive, was the fifth annual exhibit to be given at that place, and far surpassed in importance any that have preceded it.

The Chino Valley beet growers have nearly all contracted their crop for prices ranging from $3.50 to $5.70 per ton according to the per cent. of sugar shown. This is an average increase of 35 cents per ton over the prices of last year.

The State Grange of the Patrons of Husbandry decided to establish a bureau of Statistical information to collect data concerning crops and resources in various counties of the State and forward the same to subordinate granges.

Advices from Ventura state that the Lima bean crop is the largest in the history of the county. A dozen threshing outfits are in operation, endeavoring to secure the crop before the winter rains. The yield is said to be fully up to the estimate of a few week's ago and in some cases exceed it.

M. A. Carlton, one of the greatest cereal experts in the country, a member of the staff of the Agricultural Department at Washington, arrived at Berkeley a few days ago. Mr. Carlton will visit all the experiment stations where wheat is being grown and will also gain full information of all that has thus far been accomplished by the University at home.

RED BLUFF, Oct. 8—It is reported here that James Rennie, manager and superintendent of the Stanford ranch at Vina, has tendered his resignation to Charles G. Lathrop and will sever his connection with the vast estate of 60,000 acres in this country and 40,000 acres in the Gridley ranch in Butte County. Rennie's resignation gives rise to persistent rumor that this immense tract which is part of the Stanford University endowment, is soon to be divided into small tracts of from ten acres up and sold to eastern agriculturists. This property in this country is assessed at almost $1,000,000.

LIVE STOCK.

Last week 20,000 rainbow trout were placed in Strawberry Creek in the San Joaquin Mountains.

The J. E. Smith Livestock Company of Pendleton, Ore., has shipped two train loads of lambs from Meacham to Minnesota. The sheep were purchased and sent to Minnesota feeding districts.

The Ames & Garsey sheep ranch in Mendocino County, consisting of 4200 acres has been sold for about $6 per acre. The new owner, W. C. Henshaw, now has about 24000 acres of good sheep and cattle range.

Entries for the races at Tulare, beginning on the 16th, have been coming in rapidly of late, and they are assured a greater number of horses at the track during the race meet than has ever been brought together in the valley.

Livestock at the Spokane Interstate fair, October 9 to 15, will be the finest ever seen in that part of the country. The best which was shown at the Lewis and Clark show at Portland will be there besides others from the Pacific northwest.

Tulare County expects to have an unusually large exhibit of live stock at the fair, October 16-21. Failure by the Board of Supervisors to make an appropriation for a stock exhibit fund has resulted in the citizens taking the matter in their own hands and the live stock exhibit is expected to be the chief feature of the fair.

W. M. Weaver and V. P. Edie have gone to Albuquerque, New Mexico, to bring in 6,000 sheep to Imperial valley. It is their intention to ship them over the Santa Fe railroad to Temecula in Riverside County and drive them from there over the mountains by way of Warner's ranch, San Felipe and Carrizo Creek thence across the desert to this Valley.

The Corning wool sellers have disposed of all the wool stored in Kaufman Bros. big warehouse at prices ranging from 14 1-2 to 16 1-2 cents. This is lower than the growers earlier in the season expected to realize some of them hoping to get 20 cents for their clip, but the prices ruling this week were about the average and were the prices at which Red Bluff wool sold.

MISCELLANEOUS.

Holtville, on the desert, has organized a chamber of commerce.

Two inches of snow fell in the mountains of the Santa Barbara Forest Reserve on last Thursday.

A produce company with $20,000 capital has been organized at Indio, whose object is to market fruit, vegetables and other farm products.

The Home Telephone Co. has secured entrance to Oakland, which means cheap and efficient telephone service for that district.

Escondido is to have a regular "clean up" day on which all good citizens will be expected to see that their premises are above reproach.

Marysville has a large and very much alive Woman's Civic Improvement Club which is doing a world of good in making the town more tidy.

The City Trustees of Anaheim have fixed Nov. 11 as the time for holding an election to decide upon the issuance of $69,000 bonds for city improvements.

Last week's rain in the central counties seems to have caused no damage, though at some points, Visalia for instance, over a tenth of an inch fell on Thursday.

Hon. T. P. Lukens of Pasadena, long a much appreciated employee of the U. S. Forest Service, has been appointed by Gov. Pardee Assistant State Forester.

The express shipments at Escondido for the last week were 1590 dozen eggs, 1700 pounds chickens, 300 pounds butter, 570 pounds of cream, and 16,170 pounds of grapes.

A big flow of natural gas was struck last week, near Angiola in Kings County. It is only 15 miles from the new town of Corcoran and in the midst of a rapidly developing section.

Chino is on the eve of incorporation as a city of the sixth class; a petition circulated for that purpose seems to have the requisite number of signers to get the supervisors to call an election for the purpose.

The supervisors of Solano County are taking steps to call a special election to vote bonds in the sum of $300,000 for the purpose of building a new Court House at Fairfield and a branch county hospital at Vallejo.

The Woman's Civic Improvement Club has decided to plant more palm trees in the square, and the trees now adorning the Methodist Church grounds will be used for the purpose, as the Aid Society of the church is about to make some improvements that will necessitate the removal of the palms and they will be donated to the Improvement Club. (Marysville.)

The President has established a new forest reserve in Arizona, which is to be called the Tonto Reserve, and is intended to protect the watershed of Tonto Creek, an important feeder of the great irrigation reservoir to be created near Phoenix. The reserve will contain 1,120,000 acres and will extend north and south from the Magellan Plateau to Salt River and east and west from the Verde Valley to the White Mountain Indian Reservation.

C. H. SESSIONS, ASSOCIATE EDITOR

ANGORA GOAT INDUSTRY.

Writing from the standpoint of an experienced goat raiser, H. M. Williamson of Oregon gives his views on the value of the Oregon goat in a country where brush exists and the land needs cleaning of weeds. His idea is that the time is not far distant when the Angora goat industry will be larger than the sheep interest of today.

Angora goats first found favor in Oregon among the farmers of the Willamette valley, because they proved so useful as brush destroyers. In the days when the Indians controlled the country, annual fires kept the Willamette valley country free from brush, but when the fires were stopped the brush sprang up and "took the country," or so much of it as was not under the plow. Pastures became young forests and slashings and burnings were followed by a fresh growth of brush. It was found that the cheapest method of getting rid of the brush was to pasture goats on it. The Angora goat paid for his keeping by his work as a brush destroyer and his fleece and increase were profit. On many of the valley farms the period of usefulness of the Angora goat was temporary, but in the settlements among the foothills the industry took on a permanent form. Where there is rough, hilly land the humid climate west of the Cascade mountains foreordains a perpetual field of usefulness and profit for the Angoria goat. After the more level lands have been brought under cultivation the rough hills remain and tend under our lavish rainfall, to rapidly cover themselves with brush, even after they have been cleared. Permanent grass pastures for other stock are not a success on such lands without the aid of goats. In many places the tendency of brush to grow is so strong that goats will always, of necessity, be the leading domestic animal.

The logging off of timber lands by lumbermen also opens a large field of usefulness for the Angora goat, a great share of the logged-off lands west of the cascade mountains are destined to become in time farm lands. Some errors have been made, however, in placing goats upon logged-off lands too soon after the lumber has been removed. The brush which grows in the dense shade of a forest is unsuited for goat food. Two or three years should elapse after the trees have been cut in order to permit the soil to dry out, and become sweet, and for a growth of brush to develop in sunlight.

While the Angora goat is naturally most healthy in a dry climate it shows great adaptability if given proper care and attention. In no section of the United States are there fewer losses of goats reported than in Western Oregon. The conditions in Western Oregon and Western Washington are so similar that it may well be expected that goats will do as well in the one State as in the other, and in fact the few flocks in Western Washington which date back for a number of years are as healthy and prolific as could be desired. It almost invariably happens in Oregon, Washington and elsewhere, that beginners in the Angora industry in a district in which goats have not previously been kept, lose heavily the first year or two. This is partly due to the introduction of goats to new surroundings, but mainly to wrong beliefs about a goat's ability to live without any food or care to speak of. While the Angora goat probably requires less artificial feeding and less care than any other domestic animal it does need care and at times the aid of man in securing its food and no other domestic animal pays better for its food and care.

From the foundation of about 2,000 goats thirty years ago, the number in the Pacific Northwest has grown to nearly 200,000. Angora goats in Oregon, Washington and Idaho are most in demand where they have been kept longest. Nearly ten thousand farmers in the Northwest own Angoras at the present time and the number of owners increases rapidly from year to year. While the industry is most extensively developed west of the Cascade mountains there are a great number of ideal locations for Angoras in Eastern Oregon, Eastern Washington and British Columbia. There is a great future for the Angora industry in the Northwest. There are millions of acres in this vast section which can be more profitably used for goat pasture than for anything else; there are other millions of acres upon which Angoras will do useful work in destroying or keeping down brush. By the aid of the Angora many thousands of families will be able to make a comfortable home in hilly and mountainous sections where without the aid of the goat the task would be hopeless. Within a human generation it is probable that the Angora goat industry will be a greater one than the sheep industry is today in the States of Oregon and Washington, and the development of the Angora industry will promote, rather than retard the other branches of animal husbandry.

TUBERCULOSIS IN DAIRY HERDS.

The veterinary department of the Missouri State Board of Agriculture has recently published a bulletin announcing the intention to take up the work of testing breeding and dairy cattle in the State with the object in view of stamping out tuberculosis, this being done without any expense to dairymen or stockmen. Attention is called to the fact that owing to the funds being limited it might not be possible to test all herds whose owners make application, but the applications will be filed and taken up in the order in which they are received.

First, the tests will be limited to registered beef cattle and dairy herds, the idea in this being to prevent the spread of this insiduous disease wherever it is found. Pure-bred animals

Put *Facts* and *Common Sense* to work on a Tubular Cream Separator and **you know it must be easy to operate.** Put *Facts* and *Common Sense* up against a back breaking, hard to wash, high can "bucket bowl" machine and **you can't make yourself believe** it is easy to operate. are being sold and scattered continually, hence the great importance of having this class of animals healthy.

The prevalence of tuberculosis in hogs during recent years is partially responsible for the interest now being shown in cattle tuberculosis, because it has been demonstrated conclusively that hogs fed on by-products of the dairy are much more diseased than those that are not. It is, therefore, not because tuberculosis seems to be present in Missouri to an alarming extent that the department of commerce is taking up the matter, but rather to keep this disease in check while herds are comparatively free from disease. As this work, when once taken up, will likely continue until the disease no longer exists in the State, it might be of interest to our readers to give briefly the nature of the tuberculin test.

The bulletin in question says that tuberculin is a culture liquid into which the germs of tuberculosis have been introduced and allowed to vegetate. The germs of the human tuberculous patient are inoculated into the culture and allowed to multiply until the culture is thoroughly saturated with their toxic products. The culture is then heated sufficiently to kill all germs and then passed through a porcelain filter to remove them. The filtered liquid, called tuberculin, is put up in sealed bottles and does not contain a dead or living germ of any contagious disease.

Two cubic centimeters (thirty drops) of tuberculin for every thousand pounds of body weight is injected under the skin with an ordinary hypodermic syringe. Before making the injection the syringe and all needles should be thoroughly disinfected by boiling or otherwise. The syringe needle should be dipped into an antiseptic solution between injections, and the hands of the operatior and the syringe should be kept as clean as possible during the time the injections are being made.

The injection of tuberculin into a healthy animal produces absolutely no effect. In an animal affected with tuberculosis it causes a marked rise in the temperature between the ninth and sixteenth hour after the injection. The amount of rise in the temperature which follows the injection of tuberculin into a tuberculous animal depends largely upon the extent of disease in such animal. In the early stages the rise is very marked, sometimes amounting to from four to six degrees; that is, the temperature after injection will be from four to six degrees higher than it was before the injection. The further advanced the disease the less will be the reaction of the tuberculin until in an animal that is very badly diseased only a very slight reaction can be expected. It is difficult to lay down a definite rule as to just how much of a reaction should be considered sufficient to condemn an animal. In the animal least diseased there is a reaction of from four to six degrees; in the one where the disease is advanced, there is a very slight rise in the temperature. Where there are no clinical evidences of disease, a reaction of at least three degrees should be required before the animal is condemned and marked "diseased." If in a healthy looking animal there is a reaction of from two to three degrees, the animal ought to be marked "suspicious" and re-tested at a later date. If the animal shows evidences of the disease, it should be marked "diseased" although it gives but slight reaction, especially when strong reactions are had in other animals in the herd.

No one claims that the tuberculin test is an infallible diagnostic agent. No work of the human hands is infallible. It must be admitted, however, that it is the most accurate and only means we have of gaining a correct idea of the prevalence of tuberculosis in living cattle. In the use of the tuberculin test in the State of Pennsylvania, for a period of seven years, six mistakes were made in 4500 cattle condemned. The chances are that in careful hands there will be at most not more than one mistake per hundred head of cattle condemned. The per cent at most is so small as to be hardly worthy of consideration.

A VALUABLE HEIFER FROM TESTED DAM.

C. W. Leffingwell of Whittier writes us as follows:

Gentlemen: We are offering this week a daughter of Vela Hastings at a price which is very low. This heifer will probably develop into as good a cow as her dam, but to do so she must prove herself very persistent, which takes time. We are compelled to sell something to reduce the number of our herd and as our older cows are all well along on yearly tests we are compelled to let some of our heifers go. As this one has no record back of her to absolutely prove what she will do for the entire year, we are compelled to put a price on her which may prove way below her actual value. Buyers will find that our ideas are high as to the value of our proven performers, but when a man buys a heifer which has not yet had time to prove her persistency he is always taking some chances and should get some concession in price on this account.

Very truly yours, C. W. Leffingwell, Jr.

VALUE OF ALFALFA FEED.

Mr. Cotton is a well known lawyer at Portland and owner of a large dairy and in speaking of the value of alfalfa as a milk producer says: "There is no better food for cattle, and for cows in particular, than alfalfa. Ten pounds of alfalfa hay is equal to eight pounds of bran, and bran selling at $20 a ton, alfalfa at $16 a ton, it will readily be seen that alfalfa is cheaper than other feed for cows. And not only cheaper, but it is by far the best milk producer. Alfalfa is the only forage obtainable in mid-summer and the farmers of the Willamette valley (Oregon) in particular, should be educated in this one fact, as green forage at that time of year is very hard to procure in this part of the State."

THE FUTURE OF THE DAIRY.

At the dairy meeting held in Portland on the 27th of September, Dr. Jas. Whitcomb, director of the Oregon Agricultural College, delivered an address on the "Future of the Dairy" which applies quite as forcefully to California as to Oregon. Among other things he said:

"Dairying is destined to become the most important branch of agriculture in this State. This branch of husbandry is rapidly forging to the front and the products of the dairy will soon outstrip in value the wheat product of the State. Every condition conducive to successful dairying can be found here. The wide range of forage production and the equable climate combine to make conditions ideal for dairy husbandry. There are millions of acres of land in this State which intelligently managed, can be made to support a cow to the acre. A good cow given good dairy care should produce a net annual return of fifty dollars. Thus it is apparent that dairying can be made to yield fabulous wealth to the people of this State. Dairying is the ideal industry for the small farmer. It gives him constant and remunerative employment. A good cow properly fed and handled will never fail to yield a handsome profit. Another important feature of dairying is that the cow does not rob the land. Soil robbing is the bane of agriculture. The cow fattens the soil rather than impoverishes it. Plant food is the farmer's capital, hence any system of agriculture which unnecessarily exhausts this is wrong in principle.

"Large crop production is characteristic of all successful dairying districts. Thus the indirect profits of dairying are oftentimes considerable. There are systems of farming which are immediately profitable, but in the end are disastrous to successful husbandry. There are systems which enrich the father but impoverish the son by reason of a worn out soil as a heritage. Dairying does not do this, but rather leaves the soil richer for the benefit of future generations.

"Dairying quickly makes any community financially strong and insures the perpetuity of successful agriculture. The cow is the cornerstone of agricultural prosperity. If she is wisely selected and given proper care she will pay off more mortgages and build more and better homes than any other farm animal.

"The magnificent display of dairy cattle at this exposition gives to the dairyman a rare opportunity to become familiar with the highest types of dairy animals. It should be kept in mind that it does not cost any more to maintain a first-class cow than it does to keep an inferior one. The average yield of butter per cow is about 150 pounds per year, while herds of first-class cows will yield an average of three to four hundred pounds per year. Thus intelligent selection and breeding of dairy stock pay a big premium. Modern dairymen know just what each individual cow is producing from week to week or month to month and if after a fair trial a cow does not come up to a good standard of production she is sold to the butcher, or to some less intelligent dairyman. The modern dairyman is not only familiar with breed characteristics, but he also understands how to combine rations properly and economically. He also understands the value of kind treatment and the comfortable stabling of his animals. Dairying properly pursued will never fail to yield profitable returns for capital and energy expended."

VETERINARY DEPARTMENT

BY DR. W. J. OLIVER,
318 East Second St., Los Angeles.

To the end that this department may be made as valuable to the subscribers as possible, we ask observance of the following: Be sure to state in full the history of the case, location of the disease and the conditions under which the animal has been kept just before and since the disease appeared. Give your name and address, which will not appear in the paper if you so request. No charge whatever is made for such questions as are answered through the colums of the Cultivator, but when an immediate mail answer is wished Dr. Oliver asks an additional fee of $1.00 and will give immediate attention and reply by mail. In such case write Dr. W. J. Oliver, 318 E. Second St., Los Angeles, Cal.

Questions should be in by Monday to be answered in the following Friday's paper.

CHOREA IN DOG.

I have a pup that was poisoned and has a peculiar jerking motion like St. Vitus dance Is there any remedy for same?—M. S., Cambell, Cal.

This pup had distemper and now has chorea, which often follows distemper in young dogs. Give from 2 to 4 drops tinc. nux vomica twice a day after meals, according to age and size of animal. You may increase the dose to twice the amount after a few days.

A hot bath and dried and well rubbed with alcohol is beneficial.

GARGET.

Editor Cultivator:—Will you please tell me through your valuable paper how to cure a cow of garget? She is nearly dry, but I milk her once a day. She will be fresh about the 26th of October. Pus comes from one of her teats. When she was fresh last November her udder was terribly swollen and I bathed it with olive oil and camphor. I then bathed with turpentine, but the milk was not fit to use. This will be her fourth or fifth calf. Yours, —A. N. B., Gardena.

Your cow is too near fresh to recommend any treatment until after she has calved. Then let the calf nurse for a few days. Milk all out the calf leaves, give her a tablespoonful of saltpeter once a day in mash. If there is any garget use olive oil 8 oz., eucalyptus oil 2 oz., gum camphor ½ oz. Rub in twice a day after bathing.

FOR RELAXED TONGUE.

Editor Cultivator:—I have a horse that has lately gotten into the habit of letting her tongue hang out of her mouth when at work or on the road, which is very unsightly and disagreeable to see. Can you tell me the cause and remedy? The animal is 18 years old and has been an all purpose horse, used to cultivate the orchard and to drive in the family surrey. I am feeding her on new baled barley hay. She seems to be in fairly good health. An answer in the columns of the Cultivator will oblige.—J. D. P.

Have your mare's teeth examined. Very often sharp projections on teeth will cause a horse to loll the tongue. If this does not stop her, get a lolling bit. This has a flat piece of iron on, which prevents getting the tongue over the bit, which they usually do in such cases.

WORMS.

Editor Cultivator: I have a good horse that is troubled with worms, what shall I do for him?

Remedy: give one teaspoonful of the sulphate of iron in feed for six mornings.

On the seventh morning give one half pint of linseed oil with half an ounce of turpentine. Repeat in two weeks if the horse does not improve.

CLIMATE AND CROP REPORT

WEATHER AND CROP BULLETIN.

U. S. Department of Agriculture, Climate and Crop Bulletin of the Weather Bureau, California Section, for the week ending Monday, Oct. 9th.

General Summary.—Clear and warm weather prevailed most of the week in all parts of the State, with dry northerly winds a part of the time. Light rain fell in the central and northern sections, but caused no material damage to crops. Fires in the foothills east of Santa Barbara caused great damage to harvested crops and seriously injured orchards.

Raisin making is still in progress, though a large portion of the crop has been taken to packing houses. The weather was very favorable for curing the raisins and for completing the drying of late deciduous fruits. Southern California walnuts are somewhat injured by heat; the crop is reported lighter than last season's and the nuts of excellent quality. Oranges continue in first-class condition in all sections, and the outlook is good for a heavy crop. An unusually large crop of apples is being gathered. The wineries are still in full operation. Almond harvest is completed in some sections and progressing in others; the crop is reported good. Olives are in excellent condition.

In San Luis Obispo and Ventura counties the bean crop is reported the best in many years, and there is a good yield in other sections. The crop is nearly all harvested and thrashing is progressing rapidly. Hop baling and shipping continue. Sugar beet harvest is progressing. Fall plowing and dry seeding are in progress in some sections.

Eureka Summary.—Cool, with light frost at close of week. Recent rains greatly benefited feed on high ranges. Large shipments of apples continue.

Los Angeles Summary.—Conditions favorable for citrus fruits and the crop is looking well. Walnut picking begun on fair to good crop. Bean threshing progressing; crop in some localities exceeds expectations. Irrigating water is plentiful.

BUSINESS NOTES

ECONOMY IN RAISING WATER.

It is reassuring to know that underneath one's land lies a vein of water bearing gravel from which water may be brought to the surface to assure regular crops. It is, however, discouraging to find the cost of lifting the water almost prohibitive. Sometimes this is the case from conditions which may not be overcome. More often it is from ignorance of the principles which govern water lifting. Many cases are known when a farmer has "guessed" his well contained a certain supply; "guessed" a certain style of pumps and a certain power would answer, and, finally has to "guess I'll have to pull out the old and put in a new and better adapted plant."

A lot of exasperating expense and loss of time would have been saved had competent people been consulted at first. The plan of the Pacific Coast Manufacturing Co. is to supply just such information to their purchasers. They will install a plant to supply a city or one for a small garden.

A STAND-BY.

Up at Pomona recently we asked a satisfied fruit grower who was watching his irrigation while the pumping plant was running itself, that engine he used and he answered "why, the Fairbanks & Morse, of course. It's my stand-by." He added further that it is easy to start, easy to run and most economical for the power it develops.

Pretty nearly every thing in the machinery line can be had from this firm. Write Fairbanks, Morse & Co., Los Angeles, for catalogue or prices on everything in the line of machinery. Prices always the lowest for the best goods, but nothing in inferior lines sold at any price. Mention this paper when you call or write.

Waite, Bailie & Lynch, with offices and warerooms at 934-45 N. Main St., will engage in general repair work and handle gasoline and steam engines, boilers, pumps, etc. Mr. Jos. W. Lynch, who for seven years past was manager of the local house of Baker & Hamilton, has purchased an interest in the new firm and will have the business management.

The Pioneer Roll Paper Co. are now located in their handsome new quarters at 219 and 221 South Los Angeles St., where they will be pleased to meet their old and new friends.

ROAD DUST VERSUS LIME.

My description of "little mother" in last week's Cultivator was every word true, but I forgot to tell how interesting it was to see the little birds open wide their mouths when they heard her chirrup, or if they were sleeping a gentle touch on the end of the bill would have the same effect, and then the angleworm, or fat maggot, or hard-boiled egg and mashed potatoes or bread crumbs, whatever food "little mother" had decided contained the proper nourishment for each particular bird, was gently dropped into the gaping mouth every two or three hours. It was a most interesting and amusing operation to a stranger, but "little mother" was so in earnest, so faithful, loved the wee birdies so, that she saw nothing funny or amusing in the feeding of her pets. Nor did she then know and understand that she was laying the foundations of an expert in poultry and bird raising, for an expert is only a person with experience, and she was gaining practical experience which she never forgot.

It is the little things in the poultry raising which lead to good results, and I think this is the reason women usually succeed in the business where men fail.

In my last I told you I would give some of my reasons for not advising a free use of slacked lime. Old and successful poultry breeders avoid it for one thing because it will bleach out or fade the legs of the fowls, drying out the natural grease in the shanks or making the skins or scales dry and brittle. A bird with legs in that condition would be severely cut at a poultry show. Another bad effect is that, if plentifully used each time a fowl jumps down from the perch a cloud of lime dust will be raised, which is very detrimental to the lungs and a third reason is that the fowls are very apt to pick it up and eat it and this is most injurious to the organs of digestion.

A friend of mine said, "I think I will get some lime for my fowls." "Don't do it," said I, "your fowls need grit, not lime. "But it would be good for the soil," she replied. "No, your soil needs sand, but not lime." Not long after she wrote me she had bought a barrel of lime, she knew it was too much, but thought it would be a good thing to have. The following week came an agonizing letter, the fowls were eating the lime and were sick, one of the best was dead, she had held a post-mortem and found a small lump of the lime, which had eaten a hole in the gizzard and the poor bird died in agony. What should she do? "Give the others milk to drink and get rid of the lime!" She cleaned up the lime and sold the remainder, got in sand and gave them grit and had no further trouble.

A veteran poultry man said to me, "I never use lime." He sold some beautiful thoroughbred black Minorcas to a man some years ago. In about three weeks the man met him and told him he thought they were all sick, they had stopped laying and he was very much dissatisfied and wanted him to come over and see how bad they looked. He went to see them, found the pullets with sickly looking combs, tail feathers muffled out, no longer bright and glossy as they were. He looked in the henery, it was clean enough, the floor and perches covered with lime. "Why, man, they will all die if you keep them in there!" The air was full of lime and he told me the lungs must have been full. He had heard that such treatment would kill gape-worms and he felt sure his Black Minorcas would also be killed by it. Lime is excellent in its place, for white-washing henneries and barns, not for a dust bath for hens, nor for scattering on the floor of their roosting places. Road dust costs less and is greatly superior to lime or any other dust for henneries, it kills lice, absorbs and retains the ammonia and makes excellent fertilizer from the hen droppings.

It is the little things in the poultry business that tell, now if my friend had not given her fowls lime she would not have lost several, and had others so sick that they could not lay. Her losses were the cost of the lime, the value of the hens which died, and loss of eggs, probably several dozen.

As for the owner of the Black Minorcas, I do not know if he lost any, but he had his hens sick for several weeks and this prevented their laying, so he lost several dozen eggs, and had sick fowls, and when once a fowl has been sick enough to stop laying for several weeks her constitution has been seriously injured. Hens are machines and the machinery must be kept in good running order and full of energy if we want good results. Novices will recommend lime, but old breeders who have had twenty or thirty years experience, real experience not hypothetical, will say don't risk lime—use road dust.

All that cleaning up and fixing about the poultry house will be useless if you don't try to get rid of the lice and mites and leg scales on the chickens. Grease each one under the wing with keresene and lard, soak the legs in crude petroleum or a thinner mixture of kerosene and lard. The little insects that cause scabby legs must be driven out from under the leg scales.

There is mighty little money in fowls that are always kept hungry, but there is also a difference between well fed and over fed hens.

Fumigation should be part of the fall housecleaning. Sulphur in bulk is cheaper than the candles and equally effective.

Suppose the hens would all strike for a year, wouldn't many a farmer wonder where his groceries were coming from?

Fall is the best time for farmers to buy males for next season. The breeders are glad to unload their surplus cockerels that may be somewhat "off color" or may be slightly defective in other fancy points at a very moderate price if they do so early in the season.

Look out in good season for the breeding ram this fall; be sure that he possesses individual merit so that he will improve your flock.

If we were buying a cow we would ask first how much milk she gave, second what kind of milk and third if she were an easy milker. After satisfied on these points we might possibly ask what breed she belonged to.

Petaluma Incubators and Brooders
The acknowledged standards of perfection. All poultrymen who have used these machines have supreme confidence in their ability to hatch and brood. Hence their ever increasing popularity. Winners of the GOLD MEDAL at the St. Louis World's Fair for greatest hatch, with 40 different makes of incubators in competition. How's that?
St. Louis, Mo., Dec. 8th, 1604.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A FILCHER, Commissioner.
And Now Comes New Reward for Merit:
Read the following telegram received from the Lewis & Clark Exposition at Portland:
"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clark Exposition."

TO BREED GEESE.

For breeding purposes never use a gander related to the females. The geese improve up to 10, or even 15, years, but ganders get cross after their fourth year, and a new male bird may be desirable. The gander holds his head higher, has a heavier neck, but a less coarse voice than geese. New breeders do better if bought some time before needed. Till wanted they will not do as well. A gander naturally prefers a single mate, but can be coaxed to take two, or even three. Do not attempt more.

Old geese do well in all kinds of weather with nothing more than a shed for shelter. They will share the cattle shed, but are less apt to be stepped on and injured in one of their own, where they will often do their sitting, too. Early laying is not desirable, since the goslings do not thrive well unless they have an abundance of grass. Indeed, a goose is as much of a grazing animal as a cow, but the latter never likes to eat from the same field with geese.

Breeding geese should have considerable exercise, and be kept moderately thin in flesh. They cover their eggs with hay or straw, so there is a chance for egg hunting. If hatched under common hens the biddy mothers step on some at first, till used to such strange children. As soon as each gosling thus hatches it had better be put in a basket by the stove till strong, and all are out.

For the first three days water, grass, and a little bread and milk, not sloppy, are all they should try. Later scalded cracked corn is added. Keep their mother confined to a limited space the first few days, then gradually enlarge the run.

Goslings can not stand dew nor swimming till they get a full coat of feathers. They are also liable to be overcome by heat, and should always have some shade where they can retreat from the sun's rays.

Some pick geese two or three times after spring laying. In July or August is the natural time when feathers come out easily, without blood or matter in the quill. In winter feed a little oats, corn, plenty of water, grit, oyster shell, clover hay, and cornstalks cured green Leaves of the latter may be prepared in the fodder cutter and cooked, then thickened by meal. Ganders have sharp eyes and ears, and give a noisy, effective alarm at the sight of hawks or dogs.

TURKEY FARMERS' SECRETS.

An exchange says:

A farmer pointed to a small mill wherein a petroleum engine chug-chugged vigorously:

"In that mill," he said, "the feed for my 2000 turkeys is ground. The whole secret of successful turkey raising lies in abundant feeding. It keeps six men busy to feed my birds.

"They are fed five times a day, and each turkey gets as much as he can hold. Carrots boiled in lard and crushed barley and milk are very good fatteners, and the birds stuff themselves with them. Then, the last thing before going to roost, they eat all the oatmeal porridge and buttermilk they can find room for.

"Cocks cost more than hens on the market, because they are harder to raise. If they get together, they fight to kill one another, and they eat, furthermore, five times as much as hens.

"A cock, three hours before killing, is made to swallow a half-pint of vinegar. This vinegar makes his flesh fine and tender; without it, he would be coarse and tough.

"A turkey farm like mine pays easily from $1500 to $2500 a year."

The farmer'swife knows that there is money in poultry under adverse circumstanmes, but she needs the co-operation of her husband to make a success of it. There as so many things connected with the poultry business which a woman without help, cannot very well do.

Cramp and rheumatism are quite prevalent among ducks and are induced by housing them in damp quarters. Duck pens where the birds sleep at night should be fixed, if possible, where all water will drain away from them in wet weather. A duck takes to water, but let the ducks decide when to take to it.

Ducks are dandies to raise for home use or for market. While they are chicken cholera proof, roup proof, gape proof and hawk proof, they will die of their favorite diseases, spinal meningitis and paralysis.

The best time to buy breeding stock is in the fall.

The ventilation for the poultry house should come from the front or below.

The health of the chick depends very largely upon good digestion.

It is best to feed young poultry by themselves and not with older ones.

Burn up the old nest material, clean up and disinfect the poultry houses.

Feed poultry sweet skim milk occasionally during the summer months.

Feed squabs in troughs and never throw grain on the floor of the loft or fly.

The weeping of an heir is laughter under a mask.

Dry bran is a good feed for chickens the year around.

MAKE THE FARM ATTRACTIVE.

Social economists have been predicting for years that the end of the nineteenth century would see nearly all the population in the cities, but statistics tell us that the flow to the cities is about at a standstill, and probably will now return to the country. The rush and turmoil of the cities is sending more and more people to the country, where tired nerves can rest and people can live healthful and rational lives.

Now, in order to retain our own people and attract others, we must improve our surroundings. What is it that draws our boys and girls to the city? Music, art, theaters, beautiful residences with well-kept lawns, parks, where grass is trimmed to a decorous neatness and adorned with beds of beautiful flowers. What were their surroundings at home in the country? A bare front yard, or else one grown up in weeds with perhaps a few scattered shrubs or rose bushes, which were nearly excavated by the chickens wallowing at their roots, chicken feathers scattered all around, and in the back yard, most neglected of all spots on the farm, all manner of trash and dirt, broken plows, harrows and other farm trash. Even where the front yard is kept fairly orderly and neat in a majority of cases the back yard will be an eyesore to all beholders, as the Irishman put it, a Queen Anne front, but a Mary Ann rear."

Now, this should not be. The family spend most of their time in the back yard. Not once a day, on an average, do they pass through the front yard. The busy parents say they haven't time to clean up, that the burdens are heavy enough now. It will not take much time and the children can do most of the work.

Order is nature's first law. Were it disregarded the whole universe would fall. So in our small way we must have order. Have a place for everything, but don't let that place be the back yard. Keep the farm implements at the barn, where they belong. Have a store room to put all household utensils, such as tubs, barrels, buckets, mops, etc. Bury or burn all trash; be clean, and again I say, be clean. It is well said "cleanliness is next to godliness." After order and cleanliness comes beauty. We cannot have one without the other. Our yard now being neat and in order, we will undertake to beautify it by adding trees, flowers and vines. In the first place, have shade. A few trees rightly placed will shade the back door, making it cool and pleasant during the summer heat. If trees cannot be used, make an arbor, covering it with grape vines, which will yield both pleasure and profit.

WOEFUL WILLIE.

Willie's papa had some pants he bought in '92,
And Willie's mamma wisely said, "For Willie they will do,"
And then she cut those trousers down to make them Willie's size,
And shaped them here and shaped them there in a manner to surprise.
I do not say a blessed word; I never will, I vow,
But, oh, my friends, my stricken friends, you should see Willie now!

—A. J. Waterhouse in Sunset Magazine.

The good care of your stock does not stamp you as a sentimentalist, but as an economist.

General Agricultural Notes

A REFORM AT THE WEST.

The Marysville (Cal.) Appeal is of opinion that "the days of one-crop farming are passing away" in that State, the adoption of Eastern methods having been actually forced upon the farmer on the Pacific coast. The Appeal says:

Eastern people who visit California and go out into the country districts meet with surprises. If they are visitors of the observing class, the thing that most impresses them is the fact that Chinese gardeners in certain districts in the State travel about from farm house to farm house selling vegetables. To the Californian there is nothing incongruous in seeing a Chinese vegetable vendor traveling about from house to house in a country where the finest vegetables on earth can be raised, and at each house finding a ready market for the products of the soil that he carries with him. California is a country of big things, and the rancher with many acres of grain or fruit land to look after has no time to devote to such petty affairs as raising early garden truck for the home table. It would take time and money to cultivate vegetables, and it is much cheaper to buy from the gardener than to produce at home.

Thrifty farmers from the East find another source of surprise in the fact that many California ranchers who till countless acres and at the same time raise live stock, buy all the butter that is used on the family table and to supply the employes on the ranch. Like the vegetable proposition, the butter question is also easily explained.

When it comes to a matter of education, however, the Californian is not slow in grasping a situation. The younger generation of farmers see that the day of big things is past and that there is more money to be realized from diversified farming. The change is being brought about gradually. A representative of the Appeal had to travel but a short distance, from Yuba City, over the recently established rural free delivery route known as No. 1 to realize the changes that are being made. Wheat is giving place to cattle, and the acreage sown to barley and oats is decreasing year by year. Grain crops are not what they were a decade ago, and the man with progressive ideas has discovered that several hundred turkeys or a flock of industrious hens are not bad assets to have around in a year when that insidious enemy of grain known as "rust" makes its presence felt. Many wheat fields on which grain was grown in former years are being converted into fruit orchards or vineyards, and the young trees and vines look well.

CAUTION TO PURCHASERS OF FERTILIZERS.

Farmers are requested not to purchase fertilizers that are not labeled to meet the requirements of the law, and not to attempt to purchase them from any one but registered dealers or their authorized agents. Any farmer who purchases fertilizers under any other conditions does not deserve the protection of the law, and the manufacturer or dealer who does not label his goods according to the full requirements of the law is liable to prosecution and should in nowise be patronized by formers. It is quite liable to happen, and does happen, that now and then a manufacturer may miss his guarantee without intending to do so, but it is impossible that he would have his labels printed in non-conformity with the law without doing so either intentionally or through gross carelessness. Farmers can render great assistance in enforcing the law by observing the above caution.

During the first two years of the operation of the fertilizer law, some irregularities in the matter of labeling have been met with, but in all cases the manufacturers and dealers concerned have protested that they were unintentional and were the result of a misunderstanding of the requirements of the law. In most instances such has appeared to be the case; but there is no longer any reason to believe that all concerned do not fully understand the requirements of the law.—From Bulletin Number 171, Agricultural Experiment Station, Berkeley.

DESTROYING HUMUS.

In talking with an agricultural scientist the matter of the loss of soil humus came up. He lamented the fact that our farmers have so generally eliminated a large part of the humus from their soils without recognizing the process by which they were doing it. The old practice of summer fallowing, that is, plowing the ground in the spring and fall and harrowing it long enough to keep it bare in the summer, was fruitful in destroying the soil humus. The dryer and harder the summer, the more humus was destroyed. The action by which it was destroyed is a chemical one. It is usual to plow only about six inches deep. This plowing leaves perhaps an inch of the surface exposed to wind and air. This surface dries out, and from it all moisture disappears. If the surface is a fine dust, as is the case when a harrow is used in a dry time, chemical action is active among the dust particles with the result that all the organic matter is burned up and changed into gas that escapes in the air. This principle is recognized by scientists and is applied in the dust closets of residences. In such cases it is recognized that the chemical action going on in the dry dust entirely annihilates all organic matter, even destroying the last traces of paper or cloth that may be in it. Such dust, when analyzed, shows no more fertility than common dust taken from the roadway. The humus has been burned out of it. Therefore, when the field is subjected to summer fallowing and one inch is exposed each year to the action of this chemical process, all the humus which is in the soil to the depth of the plow has been annually annihilated. The fact is the disquieting element of the dust mulch wherever used. It is probable that while we are using the dust mulch to retain moisture in the soil, we are at the same time very rapidly destroying humus. This factor has not been given enough consideration in the investigations as to the use of the dry mulch. Wherever the surface soil is protected by shade trees, and the ground has not become dry enough to sun and heat, it is easy to believe that at least 16 per cent of the humus that becomes dusty, there can be no objection to using what is called the dust mulch, as it will then not be a dust mulch, but a loose soil mulch. We hear about the loss of soil humus in the continued growing of certain crops, but it is probable that the chief loss comes from the drying up of the surface soil.—Farmers Review.

SEASONING FARM IMPLEMENTS.

Now is the time to leave all mowing machines, harvesters, and other horse implements out in the field to obtain the benefit of the fall weather. Plows and harrows will, of course, be needed yet and these can be kept under cover for a while, but can be left out later during the fall plowing. This practice of fall weathering of implements is quite general in many farming sections and is encouraged year by year by a large class of farmers. It insures proper weathering of the wood and secures to the metal parts of the machinery a fine brown color. The practice is an entirely satisfactory one to the implement manufacturers as a class.—Farmer's Sentinel.

The dairy output of this State increased $2,212,596 in 1903 as compared with 1902. Counties that produced 1,000,000 pounds of butter or more in 1902-03 were as follows: Humboldlt, 3,935,786; Marin, 3,922,318; Sonoma, 2,540,489; Los Angeles, 1,996,438; San Luis Obispo, 1,369,186; Sacramento, 1,341,897; Fresno, 1,293,158; Stanislaus 1,162,561; Tulare, 1,090,448.

Have a can of clean, sweet lard at hand in the stable and if the cow's teats are chapped, apply a little of the lard immediately after milking.

Over in Redlands some people use dynamite instead of plows to loosen soil in their orchards. This fact came to light in a suit filed for a balance alleged to be due for dynamiting an orchard. The complaint set forth that the plaintiff contracted to loosen the orchard for 75 cents for each hole drilled and that he drilled, loaded and discharged 385 holes before the orchard was sufficiently opened to be plowed and trees planted.

GOOD FOR ATHLETES

The California Limited Log-Book:

Sam Solomon, of Frisco, insisted that we go East on the Santa Fe, so we embarked on the Limited. So here we are about to enter Chicago at our journey's end, and we wish to say that the "Santa Fe" is the best equipped overland route; we have traveled them all. The Fred Harvey dining service cannot be surpassed for quality, quantity and service, and the Santa Fe equipment and crew service is to be commended. We thank the train crew and the dining service crew for their kind attentions.

Yours sincerely,
Two Healthy Athletes,
MARION HART,
JACK CORMICE,
Chicago, Ill.

Queries and Suggestions

HOW TO MAKE SORGHUM MOLASSES.

Editor Cultivator:—I have ten acres of club-head sorghum which I wish to make up into molasses. What is the best step to take to obtain the same?—J. M. Holtville.

We would advise you to write the U. S. Department at Washington for the latest bulletin on this subject. However, a simple machine can be constructed which will do your work. It consists of three small iron rollers with a crank to which a wooden lever is attached, pulled by one horse, and, in addition to the rollers, an evaporating pan, which can be mounted in a crude way on masonry over the furnace. The best grade of syrup cannot be made in this way, because the heat can not be properly controlled with an open and direct fire. Second, a product of even grade cannot be obtained. This primitive method does not provide for the removal of the dirt except that which collects in the scum and is removed with it.

We would advise you to write to Toulouse and Delorieux, 618 Commercial street, San Francisco, for information as to where to purchase simple machinery.

A NEW FORAGE PLANT.

A subscriber in San Diego County whose letter we have mislaid sends in a plant from the mountains which he says the stock eats with avidity. The specimen sent, while in poor condition for botanical determination, seems to be a Clarkia, presumably C. elegans. We doubt if anything could be done in introducing this plant for stock food, at least not on an extensive scale and the work would prove costly.

SCALES AND SPORES.

Editor Cultivator: I send herewith leaves of a palm and a fern, both infested with scale insects. Please tell me what to do to get rid of same.—Mrs. J. E. L., Redlands.

The scale on the palm is easily got rid of, washing with strong soap-suds will do. We find nothing ailing the fern leaf; it is heavily covered with seed spores and as these closely resemble scale, we presume our correspondent has taken them for such.

BEAN WEEVIL.

Editor Cultivator: How may I prevent Bean Weevil from getting in my Kentucky Wonder Beans?—J. F. S., Glendora.

The only way to keep the weevil out of the beans, presuming you mean the warehouse weevil, is by keeping them in perfectly tight bins or other receptacles free from the pest. If you already have them and wish to be rid of them bisulphide of carbon is the best remedy. This must also be used in a tight bin or room, does not hurt the beans in any way; but is highly inflammable, so must be kept from fire and used during the day.

ORANGE AND OLIVE GRADERS.

Editor Cultivator: Can you tell us who are manufacturing the Orange Grader, patented by A. W. Woodward of Rockford, Ill. The patent was sold to Messrs. Fay & Stebler of Riverside, but we understand that this firm has changed.

What grader do you recommend to us. We want one that will grade both oranges and olives.

Thanking you in advance for any information in this line that you can give us, we are—Yours truly, Munger Bros., Phoenix, A. T.

The grader above noted is now manufactured by Stebler & Gamble, Riverside. The Pasadena Orange Growers' Association have one of them and are well satisfied with it.

For olive grader write to Toulouse & Delorieux, 618 Commercial St., San Francisco.

WATER WITCH NONSENSE.

A Central California correspondent writes to ask if there is any virtue in the "water witch" nonsense which bobs up serenely every twice in a while and in which some credulous people still believe.

There is absolutely no truth in the claims of these "water witch" followers. Hundreds of our best scientists have tested the matter, ever since this nonsense was first mooted, and they are unanimous in stamping the theory and practice as a humbug, not of "the first water," but of "no water."

TOO MUCH WATER.

Editor Cultivator: I planted red gum (rostrata) trees last spring when they were 2 feet high. Some of them are as high as 8 to 10 feet now and on account of their rapid growth the trunk is not able to support their tops and they bend down flat to the ground. I then put a post alongside of them 4 feet high and tied them to it so that part of the tree has to stand straight but the tops of a great many are still hanging down. Will they straighten up as they grow older or will it be better for me to cut the tops off so the nourishment will go into the trunk and strengthen it.—Yours truly, F. K.

It would seem from your description that the trees have had too much water. However, we would top them as the most economic treatemnt; cut off to a bare pole as high as you can reach and you will probably have no further trouble with them.

AN IMPOSITION.

Editor Cultivator: In view of the fact that there is a possibility that the tariff may be revised in the near future, permit me to call attention to the fact that basic slag meal, which is a most valuable and important source of phosphoric acid for a large proportion of the soil of this country, is now subject to a duty of $1 per ton. So far as I am aware, this is the first case where a duty has been placed upon a substance which is used for manurial purposes. In this instance the duty was falsely levied by virtue of basic slag meal having been wrongly classified as an iron ore. It is in no sense an iron ore, but on the contrary it is a by-product produced in the manufacture of Bessemer steel from iron phosphate. It is an imposition upon the farmers of this country that a duty was levied upon this material and the blame is probably to be laid at the doors of the steel trust. Whether the manufacturers of ready mixed commercial fertilizers were in any way to blame, I cannot say, though I very much doubt it.

Steps are being taken to have this matter brought to the attention of the National Grange for the second time, and it is my hope that you will enter upon an immediate campaign, using every possible means to have this undesirable duty removed.

Very respectfully yours, H. J. Wheeler, Director.

LODGING of grain is caused by weakness in the stalk. Complete fertilizers, rich in POTASH, produce strong stalks (making lodging impossible) and full plump grain, rich in starch and of good milling quality.

Our books are free to farmers. Let us send them to you.

Address, German Kali Works, 93 Nassau Street, New York.

Meyer Wilson & Co., San Francisco, Cal., are sole agents for the Pacific Coast.

Irrigating and Gardening.—The use of extra water in the garden is coming into use in the humid states as well as in the arid states. Wherever a stream can be turned or a pump installed with some cheap force to work it, the use of water in the garden is desirable. A little water at the right time is worth more than an abundance of water when it is not needed. The water is an assurance that the crop will not fail on account of drouth.

MAIERS WALNUT HULLER

One man can do the work of twenty. Can be moved in the orchard and worked without water and run by hand or power. Circulars free.

OCTOBER'S BRIGHT BLUE WEATHER.

O suns and skies and clouds of June,
And flowers of June together,
Ye cannot rival for one hour
October's bright blue weather.

When loud the humble bee makes haste,
Belated, thriftless vagrant,
And golden rod is dying fast,
And lanes with grapes are fragrant;

When gentians roll their fringes tight
To save them for the morning,
And chestnuts fall from satin burrs
Without a sound of warning.

When on the ground red apples lie
In piles like jewels shining;
And redder still on old stone walls
Are leaves of woodbine twining;

When comrades seek sweet country haunts
By twos and twos together,
And count like misers hour by hour,
October's bright blue weather.

O suns and skies and flowers of June,
Count all your boasts together,
Love loveth best of all the year
October's bright blue weather.

—Helen Hunt Jackson.

The Borrowed Baby.

Ted pulled his cap down over his ears and drew on his mittens. He hoped he would not have very far to go. He was out to borrow a baby, and although he was rather particular as to what kind he wanted, he did not anticipate any difficulty in finding one.

He did rather wish it was summer, for he remembered that he had seen a lot of babies in the park in the warm weather, and it would have been easy work to borrow one of those. Now, he thought, he would have to go to some house and ask for one.

He had heard the nurse say that if the baby had lived his pretty stepmother might have rallied, but as it was they had very little hope of saving her life.

Ted had not cared particularly for the baby, but he loved his new, sweet mother very much; he had been without one a long time and to be a little boy without a mother is very sad.

So he reasoned that if it was on account of the loss of the baby his mother might die—he would go out and borrow one for her, so that she could get well.

Luck was surely with him, for he had not gone very far when he saw a woman come out of a house with a baby in her arms. She stood as if uncertain which way to go. She was not a very nice woman, Ted thought, but the baby looked nice, so he stepped up to her and said: "Please ma'am, could I borrow your baby for a while?"

"Lord love it, what's this?" said the woman, and sat down on the steps. "Yer want to borrow the baby, do yer?"

"Yes, please, ma'am, I need a baby very much."

"Ho, ho, ha, ha! If that don't beat the Dutch! Yer need a baby—well, I don't. I was just wondering what place I'd better take this one to—the 'sylum or the station house. Its mother lodged in my house, and she went to the hospital and died. "Well," she said, half to herself, "if it wouldn't be an easy way to get rid of this yere kid to give it to that other one. "Here" she said suddenly to Ted, "take the baby and run along with it." And she hurried into the house and shut the door.

"Here, nurse, I've brought a baby for her so she won't die," said Ted when he marched home, very tired, but very happy at his success.

When the nurse heard his whole story she took Ted in her arms, together with the "borrowed baby," and with a mingling of smiles and tears, said: "I'll try it."

She dressed the baby in the pretty clothes of the little one that was gone and took it upstairs to the sick woman. With a sigh of content the invalid clasped it to her and went to sleep—a quiet, deep sleep which spoke of recovery.

"I suppose, father," said Ted one day, when his mother was pronounced out of danger, "I 'spose its time to return the baby." He looked troubled as he said it, for the baby had won a large place in his heart.

"No," said his father, "I think, Ted—I think we'll keep your 'borrowed' baby forever!"—Boston Post.

EDUCATING OUR GIRLS.

The father of a family of girls residing at Hollywood, was talking the other evening, on his way home, about the different dispositions in his girls. One, he said, cares nothing about household duties, but wishes to spend her time at the piano, another one prefers to read light literature and is crazy to attend the theater; the third, a real sensible, sturdy young one, about 8 years old, has the home instinct and wants to mother everything from the doll and kitten to the chickens and the calf.

This father seems a good deal disturbed because all his girls do not run to music. He is musical himself and he has an ambition to have a family of accomplished musicians which will shine in the community as a credit to his household.

Most parents like to have their daughters have at least one accomplishment, and the first thing usually suggested is music—too often it is the only thing suggested. A musical education is a very nice thing; it affords entertainment for friends, it is a source of pleasure to the girl herself and sometimes it is a means of livelihood. If a girl has a natural taste for music and her parents can afford to give her a musical education, all well and good; but music is not the only thing. Many parents have been disappointed because, after years of expense and exertion, their daughters have not become musicians, and many a girl has spent tedious hours at an instrument trying to get her music lesson. If the girl has no real taste or talent for music, it is a hopeless case, for it will be but a failure in the end.

There are so many avenues of education open to the girl of today, it seems as though one ought to be picked out which is congenial to her taste and one which she will succeed in. Drawing and painting are nice accomplishments and they fit in well in after years when the home is to be decorated and kept. If a girl shows an inclination to drawing or painting, that taste ought to be cultivated. It will make for good in mature life. Either one leads to exactness, which is necessary in every girl's life.

It may be, however, that a girl has talent for neither music nor drawing, or a competent instructor may not be in reach, or such instructions cannot be afforded, but she or her parents should not be discouraged. There are other things which are just as cultivated and just as beneficial as either music or drawing. She may become a good reader; it may be to commit and recite or simply to read aloud and do it well. With a little good instruction, one can accomplish much along these lines by herself, and there is much more to accomplish than is commonly supposed.

If we had a girl who showed the slightest inclination to floriculture we would give her place in the garden to vent her ambition in plant raising to its fullest extent. Nothing is more healthful to a growing girl than outdoor exercise, and few things mould her character more than the care of flowers. It sweetens her disposition, makes her homelike, and brings roses on her cheeks as in her garden.

But after all is said and done don't neglect the kitchen. But hear what an accomplished housewife says on this point: "The art of cooking is too often shunned, but who will question that the ability to do good, wholesome cooking is a practical accomplishment? One hour a day, the time usually spent on music, spent on any of the above-named subjects will accomplish marvelous results.

The subject chosen should be one to her liking, then each girl should carry it out with a determination to completion if possible. One mistake too often made is in poor instruction. Errors are hard to unlearn, and bad habits are hard to overcome. Poor instructors are dear in the end. A few lessons from a good teacher are far better than years from a poor one. The girl who has a general education and then becomes a good reader, is versed in literature or history, is a writer, a linguist, a penman, or a good cook is just as accomplished as the one who becomes a musician or an artist."

SPANKED AN EARTHQUAKE.

"I tried to kick the first earthquake I ever encountered," said a man in conversation recently. "It was down on a West Indian island. The table I was writing on began to joggle and I thought it was the dog rubbing against the leg. I launched a kick at him and found that I was trying to kick an earthquake.

"Well, I did worse," said a woman who had spent several years in Mexico. "It was boiling hot, and, like every one else, I took a siesta in the middle of the day. I wanted my two youngsters to take it with me, as I wished to keep them in out of the sun, but they were not always sleepy. One day they had been particularly obstreperous, rousing me from my nap two or three times. The last time I said to them, "The next one that wakes me up will get punished." I dropped off again, but in a few minutes was aroused by a cataclysm, it seemed. I opened my eyes and saw a washstand turned over, the pitcher and bowl broken and Ed standing by with a scared look on his face, which seemed to plainly proclaim guilt. I sprang up, caught him in one hand, and, with a slipper in the other, had him well spanked before his howls communicated to me the fact that I was trying to spank an earthquake."

NATURAL CHEERFULNESS.

Cheerfulness is just as natural to the heart of a man in strong health as color to his cheeks; and wherever there is habitual gloom these must be either bad air, unwholesome food, improperly served labor or erring habits of life. —Ruskin.

Old age likes to dwell in the recollections of the past, and, mistaking the speedy march of years, often is inclined to take the prudence of winter time for a fit of wisdom of midsummer days. Manhood is bent to the passing cares of the passing moment, and holds so closely to his eyes the sheet of "today" that it screens the "tomorrows" from his sight.—Kossuth.

Cookery Recipes

COOKING CHICKEN.

Baked in Cream.—Clean and cut up a spring chicken. Season with salt and pepper, dredge with flour, and place in a baking pan. Cover and cook till done, basting with a cupful of cream and a half cupful of melted butter, mixed. This is a Southern recipe.

Steamed.—Use a tender chicken for this dish. Clean it and lay it in milk and water for three hours to whiten the flesh. Wipe and stuff as for roasting, and steam until tender. Make a cream sauce, adding to it two or three chopped hard-boiled eggs and a little chopped parsley. Make the sauce quite thick and pour over the chicken.

Smothered.—Clean and cut up a tender young chicken, season with salt and pepper and dredge liberally with flour. Have ready a deep baking pan, very hot, with two tablespoonfuls of butter in it. Put in the chicken, sprinkle with flour, add a quart of boiling water and cover tightly, so that no steam can escape. Cook an hour and a quarter in a very hot oven. Do not uncover until ready to serve. Make a sauce of butter and flour and the liquor remaining in the pan; season to taste, pour over the chicken, sprinkle with chopped parsley and serve at once.—Brown Book.

* * *

Flannel Cakes.—Into a pint of hot sweet milk put two tablespoonfuls of butter. When melted, add a pint of cold milk, the well-beaten yolks of four eggs, one teaspoonful of salt, four tablespoonfuls of potato yeast, sufficient flour to make a stiff batter. Set it in a warm place to rise for three hours, or over night. Before baking add the beaten whites of the eggs, fry like any other griddle cakes.

* * *

Bread Cakes With Cornmeal.—Soak stale bits of bread in one quart of sour milk, overnight. In the morning, rub them through a colander, add the yolks of four eggs, wellbeaten, two teaspoonfuls of soda dissolved in a little water, one tablespoonful melted butter and enough corn meal to make it the consistency of griddle cakes. Beat whites to a froth and stir in just before baking. If sweet milk is used, take two teaspoonfuls of baking powder instead of soda.

* * *

Bird's Nest Pudding.—Pare and core without quartering, enough apples that will cook quickly, to fill a pudding dish; make a custard of one quart of milk and yolks of three or four eggs, sweeten, spice, pour over apples and bake. Beat the whites of the eggs to a stiff froth, beating in a teaspoonful of sugar for each egg, crown each nest or apple with this meringue, brown lightly and serve either cold or hot.

SELECTING FRUITS AND VEGETABLES FOR CANNING.

Although the canning season is practically over the following timely suggestions from the pen of A. Adel Thompson, in Farmers' Tribune on fruits and vegetables to be canned will be read with interest and may be laid away for future reference:

Many housewives have the idea that in canning fruit one may use the smaller, dwarfed, mis-shapen fruits or vegetables from the orchard or garden with the same results that would be obtained from the use of the very best. This idea is erroneous. The best material must always be used to obtain the best results. A windfall does not taste so well when eaten raw as does a good, well-formed, well-developed apple. Then why should it be any more palatable when cooked. Then again, poor fruit does not stand the same chance of keeping with the better material because of the difficulty with which well-seated, living germs are destroyed. These germs are often found on poor fruit and in fact are often the cause of inferior fruit.

Those fruits and vegetable which are the most perfectly formed and have the best flavor are the most likely to be free from germs. In gathering from the orchard there will be little difficulty in selecting the best. The greater task will be undertaken if one must depend entirely on the markets. If possible go to the public markets early in the morning; select the best looking fruit or vegetables and buy direct from the gardeners. If this is not possible, select a good reliable commission house or grocer; look over the material you wish to purchase and select that which is the most practical and economical.

Freestone peaches are more economical for canning and preserving, because less of the pulp is removed with the pit. The clingstones are the best for pickling because they are smaller and the pit clings to the pulp and so keeps the pickles from falling to pieces.

Use a medium-sized pear for canning and the large pear for pickling.

The old-fashioned crab apple seems to be fast becoming a mere memory, but in its place we have a good substitute in the strawberry crab apple. This apple should be used for pickling and if pickled a little under ripe it keeps its shape better. Many people have felt badly because the harvest apples do not have a good appearance when canned. The harvest apple may be kept intact, if pared, cut into eights and soaked in cold water over night. Then cooked in a syrup, using the water in which the apples have been soaked.

Of all fruits and vegetables canned, perhaps the one which gives the most trouble is the tomato. The trouble lies largely in the fruit selected. Tomatoes are quite susceptible to disease. Use only those which are well formed and free from black spots or specks. Select the medium-sized ones. They are less coarse in texture and of a more delicate flavor.

DO CHEAP LINENS PAY.

Every young house keeper is anxious to know whether it pays to buy cheap table linens. The Cultivator has had enquiries before on just such domestic economic matters. To enlighten the young housewife on the buying of cheap linen, read the following from S. H. H., in The Iowa Homestead:

"A young housekeeper just beginning in a modest way to keep house asks the question: "Is it economy to buy cheap grades of table-linen for every-day use, or is it best to buy the good and take extra care of it?" This young housewife reads the Home Department every week and gets many excellent recipes from Among Ourselves. She says one is certainly wise in investigating and trying to find out in regard to table-linens, for I think the table is one of the most important items in a well-kept home. My grandmother's advice to her grown-up daughters was to always buy the better quality of table-linens, as it will prove to be true economy in the end. They will retain their softness and gloss until old and worn out. To have an attractive table one must have well-laundered table-linen and it is also economy to have enough changes of linen so as not to have them washed so often. The proper way to launder is to make a good suds of tepid water and add enough good washing powder to make a nice suds or lather. Very little rubbing should be done, and they should be rinsed and hung in the shade to dry or put them out on the grass to dry. Iron with hot irons while damp.

A WOMAN BUILDS A TOWN.

Women's activities in this progressive century are practically uncircumscribed and unlimited, yet such an accomplishment as the founding and building of a town by a woman seems almost an impossibility. The impossible however, has come to pass in the steady growth and prosperity of the little town of Preston, Sonoma County, California, which came into existence through the work of Mrs. H. L. Preston, formerly a Connecticut woman, who, upon the death of her husband, less than a decade ago, found herself the owner of the homestead, a prosperous fruit farm. Possessing natural qualifications as a nurse and physician, Mrs. Preston had acquired something of a reputation in that line and many persons came to her for treatment. The necessity for providing for them suggested the idea for building a town, and a number of houses were put up. Then Mrs. Preston built a school house, and for six years taught the children herself. A church was built and she became the preacher. The needs of the little town drew mechanics and merchants, and though Mrs. Preston does not care to sell property, tenants are given a life tenancy free. No liquor is sold in the town. Mrs. Preston has had bridges constructed, the roads kept in order and new ones made at her expense. In the summer her tenants go to a lake resort she owns in the mountains, comprising a lake and ten acres of land, where camping facilities are furnished them free of charge.

The little community is prosperous and happy, and apparently appreciative of the genius and generosity of the woman who has created the ideal conditions under which they enjoy life.

It is doubtful if Mrs. Preston's success as the founder of a town has been equaled by any man or company of men, especially as contributing so satisfactorily to the comfort and general welfare of all who live within its boundaries.—Farmer's Wife.

Every inmost aspiration is God's angel undefiled,
And in every "O my Father," slumbers deep a "Here, my child."

VILLAGE AND COUNTRY IMPROVEMENT.

(Continued from First Page.)

mile, and to each owner of a 50-foot lot $5.07.

The advantages argued in behalf of the narrow and improved roadway are many, a few of them being:

First—The original cost is lessened.

Second—A sprinkling cart can cover a 24-foot pavement with one passage over it, whereas if the pavement is 30 feet or wider, it is necessary to go over the same block twice, thus doubling the cost of street-sprinkling. If the street is kept clean by sweeping, 24 feet will present one-fifth less surface than a pavement of 30 feet, which heretofore has been considered as the minimum width."

Third—There can be no question that greensward without its accompaniment of dust is more healthful for a community than a pavement.

Fourth—The wider boulevard affords more soil, more air, and more water to the roots of the trees in the boulevard, thus increasing their growth and beauty.

Fifth—The water mains, gas mains and wire conduits are in the boulvard, rather than under the paving, consequently the paving once down, need never again be disturbed.

Sixth—The narrow paving presents less surface for the accumulation of dirt and dust.

These are points quite pertinant, suggestive and well worth considering applicable to the country as well as the city.

There are in this county 6000 miles of roadway. The main driveways lead through the smaller centers of population and from thence to the greater center—Los Angeles. Well planned circuits from these smaller centers, might be devised, making delightful routes for tourists and our home people in their pleasure outings. These drives could be improved practically and aesthetically with great profit—profit in the enhancement of valuations and beneficial beyond the possibility of computation in ordinary terms. Pasadena has fifteen such circuits for tally-ho driving, which lead through groves, fields, foot-hills and neighboring valleys.

By cooperating with each other, the several boards of trade or civic leagues by united endeavor, could achieve all that is to be desired in the building and beautifying of the common highways between the principal points of the country.

This suggestion leads up to the subject of cooperation. Cooperation promotes a wider interest in human affairs. From one's outlook as a cooperator, one can see beyond the scope of his own environments, and have a more considerate regard for other agencies for the common good, besides that with which he may be immediately connected.

Clubs, or other bodies, by joining forces with other bodies, can usefully employ their abilities and exercise their sympathies. Those who are well-to-do and who have leisure can find new fields of pleasure in elevating the mind, thought and endeavor of the manual toiler, and thus promote the conception of new ideals in the minds of the people.

San Francisco Markets.

San Francisco, October 11, 1905.

Dairy.

There was a shortage of strictly fancy Creamery Butter yesterday, and the general market was in an excited and unsettled condition, with dealers scurrying around in order to secure stock to keep their trade supplied. Prices as a result were largely nominal, and in some quarters as high as 30 cents was reported for the favored brands. while conservative operators, not anxious to attract Eastern consignments in this direction, were not disposed to ask over 29c. The market closed practically bare of supplies and with a strong upward tendency apparent.

BUTTER—Per lb:

Creamery, fancy ....28@29
Do, good to choice ....26@27
Dairy, choice ....24@26
California Storage .....23 @25
Eastern Creamery .....22½@24

CORN—Good to choice, per ctl: California, new, large, Yellow, $1.45@1.50; small do, $1.60@1.65; White, $1.40@1.45; Eastern Yellow, $1.40@1.42½; White, $1.40@1.42½; mixed, $1.35@1.40.

CITRUS MARKETS

The Eastern demand for both oranges and lemons is strong and good prices are being received for everything in good condition. Some Florida and Jamaica oranges are appearing in New York, but they are still immature and have not affected the trade in California Valencias. Lemons are in short supply and are quickly taken.

New York.

Two cars of Valencias were sold Friday, and one of lemons. One car of Old Mission brand, Fullerton, were fancy, and brought $8.07 on an average. The other car was only fair, but brought an average of $3.82. The lemons were in active demand and ranged from $5.37 to $4.28 per box.

Buyers manifested much interest in Monday's auction and two cars each of Valencias and lemons were quickly taken at top quotations. Oranges ranged from $6.35 for fancy Shamrock to $2.53 for Standard Owl brand. Choice Lilac lemons brought $3.36, Warrior, ex ch, $4.79, and Rescue, ch, $3.65.

Only one car of oranges was sold at Tuesday's auction, but the fruit was high grade Old Mission Valencias and brought the top price of the season, $2652.91, the range per box being $11.37½ to $4.37½.

One car of Valencias sold Wednesday. Indian Hill brand, ex fy, average l $6.65, but Old Mission was lower.

Chicago.

Lemons held up Friday under a steady demand, the supply being moderate. Sound stock brought $4.50 and $5.00 for 360s. Oranges were quiet with practically no fruit on hand. Valencias, $4.75@3.50; Grapefruit, $6@6.50.

Oranges were steady Monday with light offerings. Some Floridas and Jamaicas appeared, but were too green to be desirable. Californias ran from $5@$4. Green Floridas, $3@3.25. Lemons firm at $4@5.

Lemons were in moderate demand Tuesday at $5@5.50 for 360s; 300s, $5.50@6; 400s, $5.50. Oranges in small supply with firm demand bringing $4@5.50 for late Valencias.

Lemons brought $5@5.50 for sound stock, with firm demand. Oranges scarce, and selling at $4.50@6.

Boston.

There were no oranges or lemons offered Friday on this market.

Monday brought one car each of late Valencias and lemons, which were quickly absorbed by a depleted market. Oranges brought $290 to $6 per box and lemons $3.50 to $5.50.

One car of lemons Tuesday, which brought $2@5.50 per box.

No citrus fruits were offered in Boston Wednesday.

Philadelphia.

No oranges were offered Friday and only one car of lemons. Extra fancy lemons brought $5.05 and extra choice $4.65 per box.

Two cars of lemons were sold here Tuesday, bringing $5.30 for fancy, $3.05@4.70 for choice and $2.65 per box for standard.

Citrus Shipments.

The total shipments to date are 29,398 cars, of which 4283 cars were lemons.

TOOLS FITTED FOR THE WORK.

Some time ago the Cultivator printed a few articles on the advantage of deep cultivation of the soil in that it let the air down into the soil, made available the fertility, prepared the soil for entrance of roots into the lower levels, thus aerating the soil to a greater depth than is done with an original cultivation. We have said that deep rooting legumes or other cover crops accomplish the same purpose to a certain extent. But it is not every year nor every farmer who will succeed in securing the deep-rooting necessary to give the best results. But any one can certainly give the necessary deep cultivation if they will get the tools which are necessary for the work and then use the power to put the tools where they will do most good. That may sound trite and be a statement of fact which anyone can see but in actual practice it must be admitted that most farmers fail first in getting strong enough tools to do this kind of work, next in putting on the power required.

The farmer who wants a subsoiler of "light draft" will have a "light draft" job of subsoiling. This lesson is being learned by a very large number of the best farmers and today instead of the six and even nine foot cultivators which were formerly used, it is now more common to see the four and five foot cultivators and even then, two heavy draft horses are needed to secure the best results in most soils.

We asked a grower recently if four good, big mules would be able to pull a subsoiler plow on dry, hard ground, and while it may be said that under certain conditions it might be possible, we believe that eight or even twelve would be nearer the truth. To accomplish the best results, as we said in a former article, the subsoiling ground should be dry so that when the powerful subsoiler if forced through it, it breaks up and allows the air to enter the lower depths. The farmer who is waiting for the rains to some to soften his soil that he may subsoil easily is making a serious mistake.

After a heavy rain the subsoiler simply shaves through the softened ground making no impression whatever other than the immediate track of the tool. Subsoiling when the ground is dry will affect the ground for several feet either side of the track of the plow. Therefore put on the mules and do the subsoiling before the rains.

As to the depth, some say sixteen, some eighteen, some twenty-four. It depends something on the formation of the soil. In any case be sure to go under the plow sole which has been formed during the summer's cultivation in former plowings. Don't irrigate too soon, but allow the air to accomplish its work before the ground is settled. Then, after the rains, unless you have sowed a cover crop, use the cultivator in a way to reach as low depths as possible.

If desired to work under the trees instead of simply adding to the width by putting on an extension and retaining all other teeth, take off as many as are in the extension. Of course, it is not necessary to do as deep work under the tree as between rows but it should at least be done thoroughly.

In cultivation we find that this deep work may not be necessary at every cultivation. That is, some follow the plan of six or eight inch cultivation, then, in a chort time, following with the weed cutter as a surface smoother, also to remove any young weeds which may be started. But as one farmer has said, let the cultivators understand that weed killing is the lesser benefit secured from cultivation. Cultivation should be to aerate the soil and to keep it in the form of a mulch to prevent the escape of moisture. The preventing the escape of moisture is plain to all but the aeration theory seems to have but few followers with the cultivators.

So far as the tools are concerned to do this work, we believe there are none which have won the favor that the manufacturers of the Killifer-Griffith Co., of Los Angeles have had. The tools manufactured by this firm are built on lines which give the greatest of strength and rigidity, built with an understanding of all conditions. Others have appeared along the line of the tools of this company but under actual wear have not stood the strain as these have. In orchard and in beet fields, also in grain and alfalfa fields they have been given thorough trials and stand the test. The old Killifer cultivator has been given trial now for many years by orchardists of the State and to meet the requirements for greater strength, which is demanded by the present system of deeper cultivation, are now built along stronger lines than formerly.

NEW HONORS.

Gold medals again won. Merit is acknowledged. The medals won at Chicago, later at St. Louis, by Petaluma Incubators are now supplemented by another medal awarded by Lewis and Clark Exposition.

F. H. Gray, manager of Petaluma Incubator Co., writes us enclosing copy of following telegram: "Petaluma incubators and brooders just awarded gold medal at Lewis and Clark Exposition."

Only a short time ago we chronicled the award to this same company of the gold medal at St. Louis exposition which award was challeged but without effect. We are not informed, but doubt not there was strenuous competition for these honors, and congratulate the Petaluma people on their success in procuring the acknowledgement of the worth of their machines. This success has been acknowledged in a practical way for many years; it is also gratifying to have it come in this more public way.

Success to Petaluma.

Mule raising is no longer confined to Kentucky, Missouri and Tennessee, but is becoming an important branch of stock raising in Indiana, Illinois, Texas and some other States, without reducing the demand or affecting readiness of sale.

LOS ANGELES SAN FRANCISCO

OCTOBER 20, 1905

AN IDEAL COUNTRY HOME.

These trees, palms, etc., when planted many years ago, cost but a few cents each; now they add thousands of dollars to the value of the ranch and cause a corresponding appreciation of all property in the community. No planting on the farm is so surely productive of a safe and sufficient return in dollars and cents; none other adds so much of beauty, comfort and protection.

CIRCULATION EXCEEDING 10,600

You You Yours

Your Business to Consider

A ton of Shorts or Bran or Chop Feed contains not much more than 180 pounds of digestible protein; while a ton of COULSON'S EGG FOOD contains over 300 pounds of digestible protein.

Now as "protein" is one of the most valuable parts of the feed for making eggs, you can readily understand that you will get more results from one ton of COULSON'S EGG FOOD than you would from a ton and a half of either shorts, Bran or Chop Feed.

Therefore, it would actually be cheaper for you and prove more profitable for you if you should feed your pullets and laying hens COULSON'S EGG FOOD every day.

Unless a food, however rich in protein, is relished, it loses much of its value.

Therefore, we make COULSON'S EGG FOOD in a condition that fowls will relish it.

They eat it greedily—THEY JUST GO FOR IT—because it tastes good to them and they like it so.

If you should feed only grain and a mash composed only of Shorts, Middlings and Chop Feed, etc., without any extras, in the way of animal foods, your average profit on your entire flock would probably not average over 75c per hen, per year.

If you should mix Beef Scraps, Meat Meal or Meat, etc., with the other feed, the profit might be increased to $1.00 per hen per year. If you should feed the hens COULSON'S EGG FOOD every day, a food that is just right, the hens will earn you a profit averaging from $1.25 to $1.50 per hen, and sometimes more, per year.

Now, if the above is true, and it undoubtedly is, one would do BETTER BY USING COULSON'S EGG FOOD, and save a lot of worry and bother of mixing feed, etc.

(1¾) Tons of Shorts at $25.00 per ton would cost $44.00.

(1¾) Tons of Bran at $24.00 per ton would cost $42.00.

Therefore one ton of EGG FOOD is equal to $44.00 worth of shorts; it is equal to $42.00 worth of Bran, or $45.00 worth of Chop Feed or $50.00 worth of Corn; and it is better because it also keeps the fowls in more active and healthy condition.

COMMENTS:

184 EGGS PER HEN

Henry Graff, a prominent poultryman near Petaluma made a flock of 1400 hens average 184 eggs apiece during the past year.

THAT'S GOING SOME

Considering the large number of hens,—as there are always some hens that are not layers.

They were fed once every day on COULSON'S EGG FOOD.

I have fed your Egg Food for the past three months to my flock of 200 pure-bred Brown Leghorns with the best results. I believe it HELPS THE FERTILITY OF THE EGGS, as I have had a higher percentage of hatches than heretofore, and can cheerfully recommend to all poultrymen.
W. E. MERCER, Ventura, Cal.

This is the first season I have used COULSON'S EGG FOOD and I consider it excellent for the purpose. Since August last I have had MORE THAN DOUBLE THE NUMBER OF EGGS I ever had before from the same number of hens. A. A. HENRY, Rumsey.

I have fed your Egg Food and had good results.
S. M. BUTLER, (Arrowhead Strain B. P. Rocks.)

I find your Egg Food proves to be just what you recommend it to be.
E. M. SHELFORD, Cloverdale, California.

Have been using your feed since last August, 1904, and have never had such a healthy, happy lot of hens before. It carried them safely through the molt without any sickness and they are laying well at present with eggs at 35 cents a dozen. MRS. E. M. HICKS.

Full particulars of your dealer. If he does not keep COULSON'S FOODS, etc., give us his name and we will tell you where and how to get them, and save you money.

A Sack of Coulson's Egg Food

The World Renowned
COULSON'S EGG FOOD

A Balanced Ration or Mixed Feed for Pullets and Laying Hens

Intelligent Feeding.

Feed the hens Coulson's Balanced Ration Egg Food. You can buy it nearly as cheap as wheat, and it will make the hens lay better than any other food.

A hen is simply an egg-making machine. Feed her properly and she is bound to lay eggs regularly. Feed as a mash one meal a day. Simply wet it up with a little water or skim milk, and it's ready to feed: it saves you time; it's the busy man's friend. Feeding a properly balanced ration the year round will yield double the profits if you feed COULSON'S.

Take the sack of Coulson's Egg Food, dump some of it out in a box—pour some water or skim milk on it. Stir it up so as to make a dry mash, (meaning not too wet), then pour it into the feed troughs for the growing pullets and laying hens. They should be fed COULSON'S one meal every day.

The supreme test of a hen is her Egg-Making Capacity. A good hen should lay about 200 eggs per year, which she will do if fed regularly on COULSON'S EGG FOOD.

Cut out this slip. A handsome needle case free.

What poultry have you? .....

Do you use Coulson's Foods? ..... If so, what kinds and how long? .....

What results have you had? .....

When will you need a new incubator? .....

Uncle Sam's Santa Ana Plant Station

Cardens Where Interesting and Valuable Experiments Are Being Made With Wild Plants From Every Land

We are constantly reminded of the paternalism of our government in many pleasant ways. One of the more common reminders of this relationship is the great number of books, bulletins, etc., which all citizens may receive by simply sending in a request to headquarters. Few of the recipients of these publications stop to think what a vast amount of time, money and labor is behind all these reports of investigations.

Down at Santa Ana Uncle Sam has a pathological station with a fair equipment of laboratory and garden, yet the public seldom hear of it. Only when something worth publishing has been demonstrated beyond all doubt, are we reminded of its existence. Prof. Newton B. Pierce, in charge of the Santa Ana station, is one of those modest, tireless workers intent only upon getting results, with neither time nor inclination to court publicity. Because the public hears nothing of him it must not be supposed that Prof. Pierce and his assistants are asleep. This is the first extended notice the station has received for some time and it may be a year or years before something worthy of publication occurs in their work. Nevertheless, the labor of these years has not been wasted and we are destined, in the next few years to have ample cause for rejoicing that we have such a station in our midst.

Prof. Pierce is now aiming, primarily, at the improvement and utilization of our native plants and incidentally in same line of work with all wild plants. As an instance, he has collected every kind of wild grape obtainable, and every country on this earth has contributed its quota. These will be used in experiments seeking to improve, and render immune to diseases, peculiarities of climate, etc., all of those sorts we have and produce new ones yet unknown and not even anticipated. It may be that new and distinct races shall be part of the fruits of this never-ending task. In addition to this there is a bed in a cloth house containing hundreds of crosses between existing species and varieties, each little pot carefully labeled with the parent names. All these brought into being for the purposes above noted.

Grapes are only one of the many families to be experimented with; every botanical species of walnut is to be found in this wonderful garden and when these have arrived at a fruiting age we may look for some entirely new sorts of high commercial value. So too has Prof. Pierce gathered the native oranges, lemons, limes, etc., of all countries. Here may be seen the largest and most robust of the citrus family, down the scale to a minute prostrate species with leaves but one-eighth of an inch long. Some of these may never produce anything but dwarf hedge plants, yet even then such will prove a valuable addition to this class of plants. Yet doubtless the experiments with the higher class of citrus trees will yield some valuable and interesting new fruits.

The writer saw here cherries from many lands, some entirely untried and unknown to horticulture and of these one or two may prove a pleasant surprise to our fruit growers even in their present state. The possibilities with plants of this class are great. For instance, many cherries, like our local insular species, have a greater value in the meat of the pit than in the pulp surrounding the pit. Such an one may be bred (and selected) toward both extremes, so that from one species we may in time get both a nut and a cherry of commercial value.

Here, too, is a collection of all the various coffees of the world. Some are more hardy and the berry of greater commercial value than any we usually find in the market. Prof. Pierce is in close touch and constant communication with botanists everywhere and he is urging those collectors, in the countries where the hardiest coffees are found, to "chase the hardier species up the mountains," with a view to getting one much hardier than any thus far discovered. If this species should yield a berry of sufficient value, the most serious feature of the problem would have been overcome. If hardiness was its only "stock in trade" it could be crossed with the best cultivated species and perhaps be made to produce a superior berry which could be successfully and profitably cultivated in California. This is his chief aim with all plants under his charge. These are no idle experiments of scientific value alone, but is is safe to say that this station will some day give to the world more of commercial value than any work ever attempted on the Pacific Coast.

Vineyard of Improved Grapes near Stockton.

Bamboos and other plants of both decorative and economic value, such as paw-paws, yams and others of importance from the tropics abound in considerable numbers, while kindred plants from the temperate zones are close beside them. The products of these two extremes should give us plants suited to any climate in this State. Australia and South Africa both contribute heavily to this collection and in addition to the more common eucalypts and acacias of the former country, are species not heretofore introduced to this coast. While the greater part of this garden is given over to plants of economic value, those of ornamental importance alone have not been forgotten. Everything from the tallest tree to the lowliest herb is in evidence and nothing will be thrown away as useless until its lack of value has been fully demonstrated by all possible experiments, both as to culture and crossing.

Prof. Pierce is very reticent about his garden work for he is not seeking notoriety or even publicity, preferring to remain "unhonored and unsung" until he has obtained results of unquestioned value. Visitors, except of a certain class, are not desired, for neither Prof. Pierce or his assistants have time to consume in showing people over the garden and no one is allowed to roam about unattended. There are two reasons for such a policy: If the visitor is of sufficient standing in the "craft," Prof. Pierce is very pleased to show him all he has and is doing; if he is not, no time must be wasted and it has been found that the public cannot be trusted alone, even in commercial places. There are always a few who cannot resist the temptation to take cutings, fruits, seeds, etc., and that without discrimination. Some thoughtless person might, in this way, bring to naught the results of years of selection or hybridization. So the scientist in charge prefers to remain, for the present, without fame, and attention, from the dear public and whenever he shall have something worthy of our notice, the knowledge of same will come to us through the proper channels at Washington.

In view of the gigantic task undertaken by Prof. Pierce, and of its unquestioned value to all the world, it is earnestly hoped that the Department of Agriculture will grant all necessary funds for lands, labor, houses and equipment so that this grand demonstration may quickly be productive of profitable results. To properly care for all the plant lines started will require, in time, several hundred acres of land. While this amount will be needed eventually, a small increase of acreage each year will allow the work to proceed as originally intended.

Aims of the State Grange

Paper Read Before the Annual Meeting of the State Grange, Patrons of Husbandry, by John Tuohy.

The annual meeting of the State Grange, Patrons of Husbandry of California, is an event of more than passing importance to the members of our order; for that reason to the State and, for that reason, to the nation.

On the 15th of July, 1873, the State Grange, Patrons of Husbandry of California, was organized in the City of Napa, the place where it will this year hold its 34th annual session. On that occasion 35 granges held charters in this State, and 28 were fully, I might properly say, ably represented. Since that date, regular annual sessions have been held, in various cities, centers of population of the State. Now it has come around to convene again in Napa City; and no doubt rests in the minds of any one of us but that the noble work of the order, commenced here 33 years ago, will be faithfully and earnestly followed up this session. The prime object then and now aimed at was: To bring together the agricultural people of California, and to unite them into a compact organization for the promotion of their own, the State's and the nation's welfare; that in their assemblies they might consider and study their interest, always being governed therein by justice and patriotism. In this way the aims of the order were, are and will always be, general in character, leaving it to time and requirements to create, develop and meet specific conditions, which would have careful consideration and give opportunity for successful work. It is difficult to state concisely, succinctly and clearly what were all the objects for which the Order of Patrons of Husbandry was organized. It was felt, however, that the educational, industrial, social and political opportunities of the farmer were very defective as compared with other classes of society; that efforts should be made to correct these defects; and that needed the assistance of the farmer class of society. That united assistance was not only necessary, but was essential to success in the betterment of these conditions. This assistance could be best rendered through united and well organized effort; and for the purpose of making that organization both perfect and efficient, it should be subordinate, State and national.

* * *

It may be asked, has the Grange bettered the conditions of the farmer, and in what way has it done so? What good has it accomplished? These questions, pertinent as they are, are never asked by the earnest patron; he well knows that the national, State and local affairs, conditions and surroundings of the farmer have been and are being promoted. That the meetings of Patrons in Subordinate, State and National Granges has promoted our social opportunities, has educated us in the study of our needs and the proper remedies therefor, has brought us more prominently before the world, has given us, as a class, a better standing therein, has taught us our own worth, and brought us our own esteem, and better knowledge of our own power when properly exercised. These things has it done and these things will it do so long as we are true to ourselves, which means being true to the order which has accomplished them for us. As a class, whatever we accomplish must be done by organization and co-operation.

The question is, what has the order done since it came into existence in Napa in July, 1873? One thing it has taught us, that in organized co-operation we achieve our best results, in the lack of that we meet our greatest failures. That much the grange has taught and is teaching us and it is a valuable education.

The Grange, (for the names Grange and Order of Patrons of Husbandry are used synonymously) has been and is now a great school, educating us in our duties and our rights as citizens and how best to perform the one and obtain the other. In our subordinate granges, every subject of public interest, except partisan ones, is considered. This consideration is a mutual interchange of views, and specific inquiry as to the merits of the subjects considered. These considerations, being non-partisan subjects, only, are without personality, and this the more readily leads to impartial conclusions. In this way every member has an opportunity of expressing his views, or of investigating the views presented before him. In this way whether diffident or pert, each has an opportunity of training himself in expressing his own views or in considering the views of the other members. The grange has trained them, and is training them to do this, and it is a very valuable education.

* * *

Co-operation is one of the greatest needs of the farming community; lack of it has been the drawback and bane of the industy. Some progress in that line has been made, but much more has to be done yet. The grange is doing its part in promulgating the true principles of co-operation; although a great deal remains to be done, grange advocacy has done much already in that line. Home life on the farm has received much discussion and consideration in the grange. How to better its social and industrial conditions has always been a grange study; for this purpose good roads are an essential, and free rural delivery is an adjunct thereof. No one feature of the rural home adds to the attractions thereof more than does good roads. The grange, by its advocacy thereof, has been the greatest factor in promoting good roads and good road laws As a result of good roads, free rural delivery of mail has come to be an institution of our land, adding to the convenience of rural homes—making rural life more attractive Grange influence originated and established free rural delivery.

Insurance against fires is a necessity of our higher civilization. This necessity has made the farmer and all others seeking fire insurance protection the prey of unscrupulous fire insurance combinations. The grange early in its life realized this; for many years fought it, and finally succeeded in having enacted legislation providing for local, rural mutual insurance. Whilst the board rates of the stock insurance companies are higher in the country than they are in cities, and whilst they are in cities from one and a half to two per cent on amount insured, in local mutual insurance companies the rates are but one-half of one per cent, every loss is promptly paid and no failure can befall them.

Rates of insurance need not be one third of what they are, greater security should come to the insured, and the State would get a large revenue therefrom. This is proven beyond a peradventure by reference to the last report of the insurance commissioner which shows the premium charged by the stock insurance companies doing business in California to be as follows. California companies charged premium of 1.64½% on amount of risks; other States doing business in California 1.52 4-10%; foreign insurance companies a rate of 1.43%; and California mutual companies .50%. The lesson taught by this showing is unanswerable, but it is still more so in other States having local mutual insurance. Take Iowa, for instance: In this State there are 117 local mutual insurance companies in 99 counties having risks in excess of $200,000,000, the charge for insurance is one dollar for writing up the policy and one-half of one mill to two mills, never exceeding the two mills on the dollar, premium on the amount of the risk. This has always been ample to meet all losses and all expenses. California can do as well as Iowa.

In Iowa, stock insurance companies, before the organization of the local mutual insurance companies, charged 1.50% premium and stoutly denied, as stock companies in California now deny, that risks could be carried for less. Now the stock companies are rustling to get risks at 75% or one-half of what they before declared was the very lowest risks could be carried for.

This change of insurance rates in Iowa is purely the result of Grange effort. Insurance against fire is incidental to our civilization and our social conditions. It is a protection that every property holder, urban and suburban should have. It should be given at the minimum rates, and to get it at the minimum, it should be done by the State. This will eliminate all charge of irresponsibility.

Taxation is an all important subject. By reason of the consideration given to it in this State Grange, it has been brought prominently before the whole community; the legislative and the executive department of the State Government. Taxation is an incident of all governments, civilized and savage, in some shape. Owing to changing conditions of society the system at one time, fair and equitable, under changed conditions of society may become unjust and burdensome.

It cannot be justly denied that every one receiving the protection and benefit of the Government should, according to his ability, contribute to the support thereof; but this the present system of State and county revenue laws cannot exact, and herein lies its inherent defect. The State Grange of California having commenced the fight for a just and equitable system of taxation should persist until it has accomplished that end. Let ability to pay be the rule of duty to do so, and that this rule may be carried out equitably a system of direct and one of indirect taxation is necessary. There should be no double taxation, for the taxpayer, who on one class of property pays a double tax or treble the amount that the other property holders do on property of equal marketable value or a greater tax than does the man who has double or treble the income and the ability to pay, is being taxed doubly and trebly.

* * *

This is not intended as a summary of what the State Grange, P. of H. has done or is doing. It is only intended to call attention to some good work it has done and some it is now doing.

* * *

The Order of Patrons of Husbandry is an incident of our twentieth century American civilization. There may be orders that fill a more conspicuous place in the community. There is none that from pure sense of duty, patriotism and devotion to right, that fills the place or does the good work our Order does.

The Grange since its organization in California has done good work—is doing good work—will do good work in the future. Duty to themselves requires it should have a larger enrollment of farmer membership. It has earned it and deserves it well.

America is under lasting obligations to Denmark for valuable information along dairy lines. There is other information that would be valuable to us if we would only avail ourselves of it. Denmark is a country of small farms. It contains 224,000 land owners, more than half of whom do not have more than one acre of land each.

LIFE OF THE HONEY-BEE.

In former years some of the most incorrect views were held regarding the natural history of the honey bee. Among other things it was believed a worker bee would live to the age of two or three years. And very many people of today do not know how long a bee does live. The Italian bee has been the medium by which this and many other mysteries have been solved.

The queen is the only perfect female bee in each colony and she lays all the eggs from which develop the three different beings found in a colony of normal conditions. That is drones or males, queen or female, and the worker bees, which are females not fully developed. The worker bees are the most numerous and are the subject of our consideration. The bee egg requires three days of incubation after which time it hatches into a tiny little worm in the same manner that a chicken hatches from the egg of a domestic fowl. The worm, correctly speaking "larva," is fed by the nurse bees for five days. It then has its size, feeding ceases and it is capped over. During the next period of twelve days it gradually transforms into a perfect bee and finally emerges as such from a cell on the twenty-first day.

Should we remove a queen from any colony of black bees and replace her with an Italian it is plain that no more black bees can be hatched after the lapse of twenty-one days, and that now all the further increase will show Italian blood. If we now keep watch of this colony we will see the black bees gradually disappearing until finally, about forty-two days from the date of the last black bee hatched, they will all have disappeared. If the experiment was made during the working season (June, July and August) in our locality, the Italian bees will have taken their places. The experiment shows that the life of a worker bee during the height of the season is only six weeks, or thereabouts. Of course during the winter bees live longer, possibly they may live nine months at most.

But in making our experiment we might have learned more about the mysteries of the life of the honey bee. If we had examined our colony on the eighteenth day after all the black bees had been hatched on opening the hive and removing the honey board or the quilt covering the honey boxes, we would have seen only Italian bees in and about them, although from those working at the entrance we might have been led to believe that the colony before us was a pure black one, showing that it is the bees above seventeen or eighteen days of age that do the field work, and those below that age doing the housework.

Even up to this day some beekeepers do not seem to realize this matter as they should. Some are still of the opinion that they can assist their bees by providing their hives with a second entrance near the top of the hive, expecting the field workers when coming home with their loads of honey to take the shorter cut through the upper entrance, and thus have a shorter route to the honey boxes, enabling them to make more trips and gather more honey.

Another scheme has lately been brought out, also based on this false theory. By some contrivance the field workers are compelled, in order to travel up to the honey boxes, to do so not by way of brood chamber, but up the sides of the hives in the bee space between the side and first comb. The writer calculated that the bees by this road will reach the outside section boxes first. They will also condescend to fill and finish them first. The outside sections are quite often not filled as well as those nearer the center of the supers. But no field bees enter the sections. The field bees deposit no honey in the combs but hand it over to the young bees or house bees, which latter use it where it seems best, the former again flitting away as quickly as possible to obtain another load, etc. It is the young bees not yet eighteen days old that under normal conditions build the comb and fill the same with honey; they also feed the larvae, the drones, the queen, and do all the little jobs that need to be done in this wonderful household.

PRACTICAL PRUNING.

The following may be counted among the practical purposes to be attained by pruning in California: Convenience of the grower, health and strength of the tree, regulation of heat and light, attainment of strong bearing wood, attainment of size in fruit, promotion of regular bearing. Examine trees with reference to their embodiment of these characters and one can hardly fail to secure rays of light upon the subject of pruning which seems dark to so many.

Trees which branch near the ground are most quickly and cheaply handled in all the operations of pruning, spraying, fruit thinning and picking. Low trees with obliquely-raising branches are more easily cultivated than any form with horizontal branches, unless the head is carried so high that the animals pass easily under the tree.

It is imperative in most parts of the State that the sunshine be not allowed to touch the bark during the heat of the day. This protection is secured even for young trees by low branching and encouragement of small, low laterals. The low tree with properly spaced branches attains superior strength by virtue of thick, strongly knit, short growth between branches, and by its strong, stiff, obliquely-rising growth sustains weight, which brings horizontal branches to the ground if needed.

The maintenance of strong bearing wood in the lower part of the tree is conditioned upon the proper pruning of the top of the tree. How far the upper levels, or the shade layer of the tree can be safely opened depends upon the local climate in each fruit region. The rule must be the higher the summer heat the denser the tree; the lower the heat the thinner the tree, but everywhere the proper condition of openness must be constantly in view of pruning.

Good fruit develops on good bearing wood and good bearing wood is the product of proper degrees of light and heat, as has just been urged. But bearing wood in the case of some fruits is new wood and reduction of old wood for the purpose of forcing the growth of new wood, must be constantly in mind.

The size of fruit, providing the tree is healthy and vigorous, depends upon the character and amount of bearing wood which the tree is allowed to carry. Removal of part of the fruit burden is done by thinning after it is well set, but this labor should always be minimized by antecedent pruning, which adjusts the retention of bearing wood according to the vigor, size and bearing habit of the tree. Thinning out of bearing shoots and spurs, when either are clearly seen to be in excess, should be the constant study of the pruner.

Regulating the amount of fruit borne in one year involves the profit of two years, because a tree cannot produce an excessive amount of fruit and perfect good fruit buds for the following year. It may generally make buds which will bloom, but not always that. If it does make the bloom, it is no guaranty that the bloom will be strong and effective for bearing. Consequently, pruning for reasonable amount of bearing should always be borne in mind and should be practiced at the close of a year of non-bearing with particular diligence, if the alternate year bearing habit is to be broken up.

It is only a little more than half a century since the honey bee was introduced on the Pacific Coast. The earlier bees in this country were the common brown or black German bee; but in 1860, the U. S. Department of Agriculture introduced the Italian bee, 20 years later, the Cyprian, and later, the Carniolan; there are others but these proved the most popular.

THE CATALINA CHERRY.

A Santa Barbara paper says: "There are not many people here who are aware of the fact that delicious wild cherries are a native growth on the Channel Islands. The fruit is ripe at this time, and yesterday a large quantity was brought across the water by the captain of the launch Irene.

The fruit is large and black and grows in clusters like fine appearing grapes. The amount of edible substance, however, is very small, as in each of the cherries there is a large seed, larger than those combined in a loquat, the layer of meat being thinner than that of a loquat. The flavor however, is very pleasant, and those who know of this island fruit seem to like it immensely. The cherries grow on trees attaining a large size."

This cherry is the one so often recommended in these columns for street and yard planting. It is one of the most beautiful small native trees to be found on the coast. It may be that it would also prove valuable as a stock upon which to bud, or if crossed with one of commercial value produce an edible fruit. As it is now, it has an exceedingly thin yet sweet pulp, and as far as its value as fruit is concerned, nearly the same amount of nutriment might be gained by sucking a china nest-egg.

THE APPLE IN AMERICA.

The first apple trees planted in America were imported by the Dutch settlement at New York in 1614. Apple trees were also known to have been growing at Jamestown, Va., as early as 1622. Until within the last half century apples were grown almost solely for cider making, as is the case today in France. As hard cider will produce drunkenness, William Penn advised his Quaker colonists in Pennsylvania to cultivate indigeneous fruits alone, as apples were then used almost exclusively for making cider or applejack.

Many of the early orchards of the pioneers of the middle west were seedlings obtained in a peculiar way. Some man whose name has been forgotten, and who is remembered only by the appellation of "Appleseed Johnny," traveled through the west and scattered among the settlers untold quantities of apple seeds. He gave them away free of charge, and he was given a hearty welcome at every cabin door.

The last decade or two has shown wonderful development of the large commercial apple orchards, and the industry has now assumed vast proportions. Apples, for instance, are exported to England and many foreign countries. Apple cores from the big drying establishments are purchased by eastern buyers and shipped to France to be used in the adulteration of wines and champagne. A large part of this champagne and wine is shipped back to America.

The Imperial Press is working with an idea of gaining a horticultural experiment station for that town.

LIME, SULPHUR AND SALT WASH.

For winter use upon deciduous trees for pernicious scale, curl leaf, peach moth, etc., the following formula is properly prepared and used will prove an effective solution:

Unslacked lime, 40 pounds.
Sulphur, 20 pounds.
Stock salt, 15 pounds.
Water to make 60 pounds.

Directions.—Place 10 pounds of lime and 20 pounds of sulphur in a boiler with 20 gallons of water, and boil over a brisk fire for not less than one and a half hours, or until the sulphur is thoroughly dissolved. When this takes place, the mixture will be of an amber color. Next place in a cask 30 pounds of unslacked lime, pouring over it enough hot water to thoroughly slack it; and while it is boiling add the 15 pounds of salt. When this is dissolved add the lime and sulphur in the boiler, and cook for half an hour longer, when the necessary hot water to make the 60 gallons should be added.

Follow the above directions carefully, particularly the boiling, if you desire success. Use this remedy as late in the season as possible. The best results will be obtained by spraying just before the peach trees burst into full bloom. On cloudy, moist day blossoms will not be injured by this wash, but in dry weather with north wind blooms will be damaged.

MANURING STRAWBERRY.

Editor Cultivator: How would the following plan work for strawberries on comparatively level land? Make shallow basins, say enough to flood the ground, land to be, smooth no ridges. First cover with 2 or 3 inches good stable manure and then with 4 or 5 inches of straw, after which set the plants through the mulching and remove by hand any weeds which may come up. Seems to me the ground gets too hot in the summer for strawberries unless irrigated all the time.—H. W. C., Escondido, Cal.

To the above question W. M. Gray, of Gardena, the successful strawberry grower, makes answer. (Editor.)

Judging from the teaching of my own experience, the growing of strawberries under the above described conditions will not make a success. Take virgin soil which has never been irrigated and will produce good barley and wheat crops and you will have a soil, if thoroughly irrigated and cultivated to make a perfect strawberry.

Covering the ground with straw is of no benefit except to retain moisture and a good mulch of fine soil made so by shallow culture is what I should advise.

There are a number of reasons for not using the stable manure and straw culture.

The climate at Escondido is not too hot for most varieties to do well. The Lady Thompson may not do so well there as at the coast where it makes a fine berry.—W. M. Gray, Gardena.

Dinuba will have a farmers' institute on November 1 and 2, at which Prof. Bioletti will give talks of special interest to the vineyardists of that section.

"U. S. Department of Agriculture, Climate and Crop Bulletin for the Weather Bureau, California Section, for the week ending Monday, October 16th."

Dry and generally clear weather prevailed during the week. In the interior of the State conditions were favorable for raisin making and friut drying. Good progress has been made in both directions and the second crop of raisins is nearly out of danger. In the southern part of the State and also in the northern orange belt conditions have been ideal for developing citrus friuts. These are all in excellent condition and there is a promise of very large crops of first class fruits.

Large shipments of table grapes continue, and the apple, late pear and quince crops are coming in nicely. The apple yield is generally heavy and of good quality. The season has been a good one for beans and a very large crop has resulted, most of the crop being already harvested. The walnut crop is about two weeks late but will be one of good quality and fair yield. The yield of honey is larger than that of last season. Olives are in fine condition.

Plowing and seeding are progressing in the northern part of the State. The absence of rain is causing some anxiety among stockmen. There is however a large supply of hay on hand.

Eureka Summary.—The weather the past week was generally favorable. Grass is making slow growth. More rain is needed. Apples and pears are being marketed in large quantities. Fall plowing is progressing.

Los Angeles Summary.—Farm work is generally at a standstill awaiting rain. Thrashing is about finished. Bean thrashing continues; will be finished in about two weeks unless rain comes; the yield is generally heavy and the quality good.

KADOTA FIG.

Mr. S. H. Taft of the Semi Tropic Nursery of Sawtelle hands us a sample of the Kadota fig which he has been producing for a few years and we find it of excellent sweetness with most tender skin and would be a most desirable fig to eat from the hand.

His ad. appears in this issue and will be interesting to those who wish a desirable fig for family use.

A grower at Brawley has a sweet potato field which has averaged over 25 pounds to the hill, or over 30 tons to the acre and he has sold them for two cents per pound. Evidently Brawley is "in it" for sweet potato growing.

California Concord Grapes and Kadota Figs
The undersigned makes a specialty of propogating the new variety of table grape known as the California Concord, and has 2000 vines for sale. Also the Kadota Fig Tree, which while resembling the White Pacific, is larger and sweeter, and the tree much excels the White Pacific in vigor of growth and productiveness. I have also my usual supply of soft shelled English walnut trees raised from selected nuts. S. H. Taft, Semi-Tropic Nursery, Sawtelle, Cal.

BLUE GUMS
Cypress, Budded Loquats, Citrus stock and Shrubbery for sale in any quantity.
Geo. B. Warner, Santa Ana, Cal.

Berry Plants and Grafted Walnuts
Grafted Walnuts on both the Native Black and English Walnut Roots. Also Santa Barbara Softshell Seedlings. Crandall Blackberry, Brandywine Strawberry and Loganberry Plants. Prices on application.

CITRUS FRUITS

By C. A. Day, Pasadena

ORANGE ORCHARDS OUT OF CONDITION AND NON-PRODUCTIVE.

Such orchards are frequently met with in the citrus districts of California. This condition is that which is sometimes termed die-back, the result of underlying hardpan or impervious clay, or excessive wetness or dryness of the sub-strata surrounding the deeper roots; or the rise of water from below or in cases of over irrigation. Where it is a case of permanent hardpan underlying the surface, it is usually considered a hopeless case; the orchard should not have been planted upon such soil. In one case which has come to our notice, a ten-acre orchard of orange trees was set out twelve or thirteen years ago on a tract of high sloping land underlaid with a hardpan strata, it being necessary to blast out the holes in which to set the trees. The orchard has not been plowed for a number of years, but has been constantly and thoroughly cultivated and fertilized every year, and the surface by frequent irrigations kept in a condition that has resulted in the production of good crops of fruit every year, and the fruit produced has been of excellent quality. The roots are of course near the surface, but the surface soil in which the root system is located is kept well fertilized and irrigated and never allowed to dry out. In this case the subsoil is hard and dry. When the trouble is due to poor drainage or over irrigation the remedy is to give better drainage and cut down the supply of water and give deep, thorough tillage. We have other cases where orange orchards have borne well for a number of years and then followed light yields of fruit, but little growth of new wood, and the trees became full of dead wood; the balance had scanty foliage.

Sometimes this condition is due to improper culture, starvation through the exhaustion of the natural plant food in the soil, and the failure to fertilize. In other cases it is the result of old age; trees that require special treatment to renew the root system and the fruit-bearing wood.

Along the line of non-production we have the following letter from C. S. J., of Orange county, addressed to the writer, which I take the liberty to answer through this department.

"The trees were set out twenty-three years ago last spring. They were Australian navels. Nine years ago I had them budded to Washington navels. They bore well for five years, since which they have been shy bearers. The soil is sandy alluvial and was covered with cactus. I have fertilized freely with cow manure but without results. I have sown Prussian blue peas which are now coming up. I am thinking of fertilizing with ground green bone and blood. I have used ———— commercial fertilizer and I pronounce it a fraud.

What do you think of my idea and when would you recommend the application of the fertilizer, and how many pounds to the tree? I have an abundance of water."

Our friend writes that the free application of cow manure and a certain brand of commercial fertilizer have been without effect and pronounces the commercial fertilizer used, a fraud. Why not say that the cow manure was a fraud as well as the commercial fertilizer? Both failed to produce the desired effect. It is my opinion, from the statement, and without knowing the full particulars of the culture given, that there is something else at fault than the fertilization.

He suggests the application of ground green bone, a nitrogenous fertilizer, and has some in the orchard peas, which if inoculated with the nitrogen bacteria, will give a good supply of nitrogen for the growth of new wood. From this I am led to believe that the trees have failed to grow annually a good supply of new wood and perhaps are today scant in foliage. If so he is on the right track as to fertilizing.

It would have been better, in my opinion, to have applied an available nitrogen fertilizer before, or at the time of sowing the peas, in order to stimulate a strong growth of peas, which would give nitrogen for the growth of new wood.

In this case he would not need a later application of nitrogen or humus as the peas would furnish both. From the age of the trees, 23 years, and from the fact that free application of cow manure and commercial fertilizer has been without effect, I am inclined to believe that the old root system of the trees, enfeebled by age, require a severe root pruning. Plow deeply and cut the fibrous roots; then by the application of nitrogen fertilizers (the peas should give this) force a renewal of the fibrous root system of the trees.

In the case of old citrus trees, or in fact all fruit bearing trees, the old, enfeebled wood past the age of bearing should be gradually removed and replaced by a growth of new wood that will become fruit bearing. The same conditions exist underground with the root system. Pruning the roots by deep plowing will induce a growth of fresh young vigorous roots that will push out in every direction in search of plant food and will renew the vigor of the whole tree.

A severe root pruning of the orange will likely be followed by a light crop of fruit and the whole force and vitality of the tree will be employed in growing a plentiful supply of new wood that will later become fruit-bearing wood.

It is necessary to adopt a method of culture, fertilization, irrigation and pruning that will annually produce new wood, in order to continue to produce regular and full crops of fruit. Whenever an orange tree ceases to grow new wood and the tree becomes full of dead wood and with scanty foliage, it is a sure indication of a light crop of fruit for the year to come

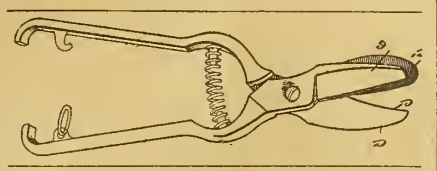
* * *

More About the Gum Disease.—The other day a citrus fruit grower reported to the writer the development of the gum disease where the irrigation had been in basins about the trees. Where it is absolutely necessary to make the basins around the trees a mound of dry earth should be banked about the trees, keeping the water from coming in contact with the trunk of the tree. It is far better to make the basins for irrigation between the trees as there is less risk of the development of the disease; it will also avoid the formation of a mass of fibrous roots directly about the tree and will put the water where it will best reach the feeding roots. One orange orchard at Duarte has been reported as destroyed by gum disease, and the orchard was irrigated by basins directly about the trees. It is decidedly the safest way to keep the water away from the trunk or base of the tree.

LESS CLIPPER FRUIT CUT.

Recently speaking of the Steffa orange clipper, which will prove a saver of bruises and cuts which have caused much California fruit to decay in transit, we give in this column an illustration of this simple little tool, from which may be gathered a better idea of its simplicity and capacity for effective work.

Just a word of description may make the illustration a little more plain. The lighter blade marked c c, also its



mate, the heavier shaded blade marked c, are fastened to the lower handle, in other words are stationary in their relation to each other and, also, with a V shaped opening. the other blade cuts across and shears past the edge of the blade marked c, making a clean cut and short stem. Now then, the point with the extra V shaped blade with points rounded and much longer than the cutting blade, prevents any possibility of clipping the fruit; in fact it is not possible in any way to bring the cutting point in contact with the skin of the fruit so as to clip the skin in the slightest, thus preventing the clumsiest worker from injuring the fruit.

It will be seen from the illustration that the tool is very light, can be cheaply manufactured and has no complicated parts which will in any way prevent the ordinary worker from accomplishing the best results, and a letter to Mr. E. P. Steffa at Pomona will bring additional information regarding this tool.

TREES FOR COUNTRY HIGHWAYS.

It is generally conceded that nothing will give better evidence of refinement, of welfare, in any community, than having its roads neatly kept, oiled, and lined with trees affording protection during the hottest days, and pleasant rest to the eye with their greenery all the year round. On this particular point we must confess that we are far from being to the front in rural California. Can this be justified enough by the fact that we do not need trees in the free air of the country streets as much as in cities?

The greatest fault to be found, even in planted districts, is the fact that every one plants for himself, without regard to the needs of the proposition or the wishes of neighbors or public. On whatever street you go you are sure to find a portion planted with costly palms, perhaps with a neat lawn border, then a stretch bare of trees but teeming with weeds; on the other side the disfigured remnants of some old pepper trees; or if anything has been planted, the most extraordinary promiscuousness of plants wondering at each other how they could have been put in line together; not to say anything of the treatment (or lack of treatment) most of them receive after having been set out. If one were to attempt statistics of the different sorts of plants to be seen on our highways and streets figures would run into the hundreds, while the number of trees recommendable for street planting is very limited indeed.

Coming to the practical selection of trees, several questions will arise. First: must we give preference to evergreen or to deciduous trees? Nature itself will give the best reply: In our climate the great majority of native vegetation is evergreen; but we have a few deciduous trees; and we would suggest that the largest number of roads be planted with evergreen and a very few of them with deciduous trees. Rainy days are too unfrequent with us to make evergreens objectionable. In regard to deciduous trees the most desirable will certainly be those that will lose their leaves in a comparatively short period, the same requirement applying to evergreen trees which shed their old leaves at different seasons of the year.

Other requisites to make a good roadside tree will be for it to stand the force of the wind, so as not to be easily uprooted, nor its limbs broken; to grow naturally compact and not to require too much artificial trimming; to possess a rather slender trunk so not to take too much of the sidewalk; to be fairly free from scale and attacks of other parasites that would deface its appearance, and last, not least, to stand well long periods of drought, and to have such texture of leaf as will not accumulate and retain too much dust.

Good humor and generosity carry the day with popular heart all the world over.—Alexander Smith.

FLOWERS ALL THE YEAR.

"God Almighty first planted a garden; and, indeed, it is the purest of human pleasures, it is the greatest refreshment to the spirits of man, without which buildings and palaces are but gross handiwork; and a man shall ever see that when ages grow to civility and elegancy, men come to build stately, sooner than to garden finely, as if gardening were the greater perfection. I do hold it, in the royal order of gardens there ought to be gardens for all the months in the year in which, generally, things of beauty may be then in season."—Francis Bacon.

In California there is no reason why we may not have flowers in bloom during every month in the year. It costs but little to get started right, and it is just as easy, just as cheap, to do the work in the country as it is in the city. In fact, it is much easier, much more convenient, to garden in the country. Do not be deterred by fear of cost of material or possible labor involved in the proper care. In our query department this week will be found a list of herbaceous perennials that require but little care and from this list might easily be obtained, through experimentation, a small number of the best which would keep up a succession of flowers throughout the year. Try it; touch up the dull colors of the farm yard, the dark sombre green of trees with a few dashes of bright color; in fact, have more flowers everywhere.

BACK TO THE COUNTRY.

It affords the nature lover much satisfaction to note a healthy yearning among our city folk for country life or for country conditions in the city. Relief from the nervous strain of artificial city life is afforded in no way so agreeably and conveniently as by a ramble amid the natural scenery of the foothills and canyons, and by the leisurely contemplation of the landscape. There are many workers in a city who suffer more or less from nervous strain, though often they are not fully aware of it. Where a large public park, with ample provisions of natural scenery, has been created, it has never failed to be much frequented for this purpose and to afford untold benefit to those who use it.

If the country is made sufficiently attractive with oiled roads, lined with trees and flanked by attractive front yards, we need have no fear for results. Such districts will soon prove irresistable that city people build suburban home and later the trolley car completes the transformation. It pays to beautify the country as well as it does the city.

Not only are the quiet and seclusion of the country necessary in a large park, affording opportunities for occasional relief from the nervous strain of city life, but they are necessary to the enjoyment of the landscape of the park, or the people will visit the country. Therefore, not only should conspicuous artificial objects unnecessary for the convenient use of the park be excluded from its natural parts, but noisy and dangerous occupations and amusements should also be kept out of, at least, the middle portions of a large park.

We are, unfortunately, too much inclined to spend a holiday in seeking some more or less exciting pleasure. A quiet drive or stroll in the country, with perhaps a family picnic under the trees, would be far more restful and therefore more rational than to rush off to some sea-side resort, with its various artificial attractions. Let us assist nature to reclothe herself by covering the bare spots made by man with ax and fire. Let us align the man-made streets with suitable shade trees, and we will have done much toward encouraging the already healthful, growing move "back to the country."

GROWTH OF TREE PLANTING.

A subject ever old and yet always new, one which more and more each year draws the attention of men and women and children, not only in our cities where their value is untold, but also in our country places we are beginning to realize the wonderful value of trees, tree planting, tree growth and tree preservation.

It is a strange fatality of our Western civilization that we first destroy what nature has so abundantly given us, then after we have wasted our forests in riotous destruction, we begin to repent like the prodigial son, and lament the grand old trees of such marvelous beauty, such wonderful proportions which we have so wantonly cut down. The young forest, sprouts from old stumps, wild shrubs, plants, flowers and weeds as well, become the things sought after. It is true of tree life as with other matters pertaining to our existence, we know not what we lose until it is lost.

The more advanced civilization becomes, and the more we understand what the loss of trees means, the more we lament their destruction and the more anxious we are to replace them. These-tree planting societies all over the land, these studies of nature now being instituted in all our schools are grand stepping stones to practical tree planting. What to plant, how to plant, when to plant and where and how to properly handle, are all subjects that cannot too often be told to the people, for it is truly deplorable how little is known about these matters by many of our people. One point however, all are learning and that is the immense value of any and all trees planted in California, either for ornament, shade, timber or fuel.

CHARMS OF THE COUNTRY.

As civilization advances the influence of natural beauty as an educating, refining and soothing force is more universally recognized. The city dweller, alert with business cares and occupations, or wearied with the continual noise and ceaseless clash of action, finds infinite rest and refreshment of mind in going out into the quiet byways of nature, where he can behold beautiful scenery and look out upon broad and pleasant landscapes. He finds in this natural beauty a sense of mental delight, and a soothing influence which affords temporary relief from the worries of the fevered life of the city dweller.

Quiet pastoral landscapes dispel the unrest born of too constant contact with care, and there is nothing that will so quickly dissipate the feeling of fatigue and discontent that is so apt to seize upon men when weary, as a few hours with Nature, where we are surrounded by the dignity and beauty that abounds in a grand park. It is better than medicine. It is the very restfulness of rest.

TULIPS AND DAFFODILS.

The U. S. Department of Agriculture has shipped Carl Purdy of Ukiah, 12,000 daffodil and tulip bulbs which Mr. Purdy will plant and cultivate at the request and for the benefit of the Department.

The object of the experiment is to determine whether these bulbs can be grown here successfully from a commercial standpoint.

Last year Mr. Purdy grew the best tulips in the United States and his plants were as good as those brought from Holland, which country has heretofore had a monopoly of the bulb business.

THE MONTEREY CYPRESS.

Cypressus macrocarpa is known to most people only as a hedge plant and a tax upon their time and resources to keep within its allotted meets and bounds. In this form much familiarity may have bred some contempt; a state of mind that the few isolated specimen plants are certainly not responsible for. Where ample room is accorded this cypress it makes a tree of magnificent proportions.

SPRAYING FOR POTATO BLIGHT.

A New York experimental station bulletin gives the details of 58 experiments in different parts of the State, in which increased yields of potatoes due to spraying are reported. At Geneva 5 sprayings increased the yield by 233 bushels per acre, while 3 sprayings gave an increase of 191 bushels. At Riverhead the gain due to 6 sprayings was 96 1-3 bushels and to 3 sprayings 56 1-2 bushels per acre. At this place the flea beetle was the principal enemy.

In experiments carried on by farmers in different parts of the State, gains of 62 1-4 bushels per acre are reported in one series including 180 acres. This gain was made at an average cost of $4.98 per acre, and the net profit, based on the marketprice of potatoes at digging time, was $24.86 per acre. In another series of experiments carried on with 41 farmers throughout the State, including 363 3-4 acres the average gain due to spraying was 58 1-2 bushels per acre, the net profit received being $22.01 per acre.

Different fungicides were tested in these experiments, soluble Bordeaux mixture and soda Bordeaux being compared with Bordeaux mixture made with lime after the usual formula. The results obtained were in favor of the use of the lime Bordeaux, as previously described. It is believed that the efficiency of the soluble Bordeaux mixture may have been reduced by the use of too dilute a solution.

The authors state that the practice of spraying potatoes for the control of blight is on the increase in New York, and many growers are preparing to spray who have hitherto disregarded this precaution. For 1905 the regular experiments will be continued at Geneva and Riverhead, and efforts made to extend the work through volunteer cooperative investigations.

GINGER

The cultivation of ginger has been tried in our hot interior valleys and resulted in failure. The reason seemed to be due to the dry, hot atmosphere. It was grown where it received an abundance of water, but the tops persisted in dying back, having the appearance of having been scalded .The fact that the best ginger of commerce comes from the West Indies would indicate that it requires the sort of climate that prevails in those islands. The West Indies became famous for their ginger early in the sixteenth century, and they and the neighboring islands still hold the reputation for perfection in that crop. It may be successfully grown along the coast and thrives fairly well in Los Angeles but it is too cold for its profitable growth on a commercial scale.

TOMATO ORCHARDS.

To raise a tomato orchard set a stake by the plant and only let the main stem grow. As other stems appear in the form of shoots from the main stem pinch them off as fast as they come. The vine as it grows is tied to the stake with common cotton strings. Three or four tyings will carry it to the top of the stake, four feet from the ground. Then the bud is pinched out. This gives a plant with twelve or fourteen large leaves four times the size of the ordinary tomato leaf and five or six large clusters of magnificent perfect fruit. In the bearing season the patch looks like a diminutive orchard loaded with fruit. Some growers like to have two stalks to the stake. In case this is done be sure to leave the vine below the first blossom as the fruit bearing vine, as it is much more prolific than any other vine that starts on the plant.—Progressive Farmer.

EGG PLANTS.

In all frostless or nearly frostless localities we should have egg plants in fruit all winter. Until recent years this valuable and now popular fruit was little appreciated but at present the demand is not only great but growing. The crops obtained are sometimes enormous, the plant being thickly covered with fruits ranging from three to five pounds in weight. The plant will endure great heat or drought, but not both at once. It does not like wet feet, but in other respects is of easy growth, not being very particular as to soils.

ROSELLE.

Roselle fruit pods for making jelly can be picked either ripe or while the pods are still green. It is more convenient to gather the pods while green for making jelly, as the seeds are then still full of the gelatinous material which enters into the jelly and are as good as the red pod. There is always color enough in the outside pods to give the red hue to the jelly.

PLANTING POTATOES.

When the tubers are planted one foot apart in the rows and the rows three feet apart, and whole tubers that weigh four to the pound are used, it requires 3600 pounds of seed; half tubers, half that amount and quarter tubers one-fourth that weight. The usual weight of seed pieces is about one and a half ounce. When potatoes are quartered lengthwise they give the best results. Large potatoes have fewer eyes than small ones in proportion to their weight ,and this makes a difference in the amount of seed required per acre. It will vary from 900 to 1800 pounds per acre.

VEGETABLES AS MEDICINE.

Watercress is an excellent blood purifier.

Lettuce has a soothing effect on the nerves, and is excellent for sufferers from insomnia.

Tomatoes are good for a torpid liver, but should be avoided by gouty people.

Celery is a nerve tonic; onions also are a tonic for the nerves.

Spinach has great aperient qualities and is far better than medicine for sufferers from constipation.

Beet root is fattening, and good for people who want to put on flesh. So are potatoes.

Parsnips possess the same virtues as sarsaparilla.

Cranberries are astringent, and correct the liver when it is suffering from inaction caused by overeating.

Dates are exceedingly nourishing, and also prevent constipation.

Apples, carrots and Brazil nuts are excellent for sufferers from constipation.

Asparagus stimulates the kidneys.

Bananas are beneficial to sufferers from chest complaints.

Celery contains sulphur and helps to ward off rheumatism.

The juice of grapes is laxative, but the skin and seeds are likely to cause constipation.

Honey is a good substitute for cod liver oil.

The juice of a lemon is excellent as a gargle for sore throat, but should not be swallowed.

Carrots are good for those having a tendency to gout.

DON'T LEAVE THE OLD FARM.

Pathetic, beyond description, is the message left behind him by a young man in Indiana, who committed suicide last month. "Don't leave the old farm," was the dying admonition of one who had left his happy farm home for the pleasures and other allurements of city life. At the old home his life had seemed dull and without interest. The daily humdrum of details had bred dissatisfaction into his surroundings. On his occasional visits to the city he had seen the troops of well dressed, fine looking fellows of his own age who appeared to take life easy, without the expenditure of effort. The elaborately dressed young women on the streets seemed prettier than the girls at home. The music halls, the theaters, the brilliantly lighted streets and the moving throng of people attracted and made his farm surroundings seem tame and repulsive. The dangers lurking behind all the glitter, the poisons that tainted all the joys of strenuous town life he failed to see, or possibly seeing may have thought himself able to withstand. It was the same old story of a weak boy, strong in his own conceit, drawn into the whirlpool of a false and frivolous life. The same old details of fast living, leading to recklessness of the extremest kind, until finally, death by his own hand. This true story carries its own moral, but fortunately for us his dying act was one to commend him to our warmest sympathies. His last moments were spent in penning the admonition above for our warning, "Don't leave the old farm."—The American Farmer.

LIKE HONEY DEW is the HIMALAYA BERRY

Coreless and rich, they literally melt in your mouth—You can have them in your garden at almost no cost

It's black, but not a blackberry. It's a new arrival, from the north slope of the Himalaya mountains. For many centuries the natives of mysterious Tibet have been making wine and cordial of them, and only the recent invasion by British troops of the "Roof of the World," as this quaint land is called, has brought this delightsome, luscious fruit to our civilization.

Enormous clusters of large-sized berries ripen all summer on this bush, making the Himalaya the most productive of any variety known. The flavor is sweet and of unusual richness. They have no core, and when ripe they literally melt in your mouth.

JELLS EASILY

For pies and jellies the Himalaya berry is a perfect success, being ahead of any similar fruit. It jells easily, and either fresh or cooked is good for the sick, being an excellent regulator and having tonic and medicinal properties of unusual virtue.

The severity of their native climate has made the berries hardy, and both the plant and the fruit will stand extremes of heat and cold better than will our domestic fruits.

WILL BE THE FAD

It will be hard for you to realize what a treat is a dish of these new berries. They will be all the fad after they get to be better known and enough are grown in the United States to supply the demand.

Now is the time to plant, and you will have a crop of berries next season. Three bushes will produce all the berries a family can eat.

We have a limited supply of pot-grown roots—hardy plants with lots of fibrous roots—not suckers, but well-grown, well-developed specimens. If you want to be the first in your neighborhood to have Himalaya berries, order now.

PRICE (Prepaid)—Per root, 50c; three for $1.00; per doz., $3.00.

Order now—the supply is limited. Use this coupon:

The Pathological Laboratory.—The commission, provided by the last legislature to locate a Pathological Laboratory and Experiment Station, met in Los Angeles last week and took testimony, so to speak, from the representatives of half a dozen localities desiring the institution.

Gov. Pardee, President Wheeler and Dean Wickson, of the University of California, constitute the commission and they sat en-bank, as a court, to hear and determine as to the merits of the competing towns. It developed, during the discussion, that the appropriation of $30,000 may be expended in two directions.

First, for the establishment of an experiment station.

Second, for a pathological laboratory.

The point most effective, it seemed to us, was the one made that the pathological station shall be located where there is the greatest diversity of pests. No great amount of land is necessary, but conditions must exist which will make this station meet the purposes for which it is to be created. It is not necessary to have expensive buildings either, but it is essential that the laboratory shall be provided with the necessary equipment to make satisfactory experiments.

The commission appears to understand what is needed and we have no doubt will make a satisfactory selection when its mind is made up.

* * *

Let Us Be Satisfied.—It has been the fear of a great many men, in this country, this year, that the United States would experience a reaction in business matters before the end of 1905 Indeed, it has been openly phophesied that we are on the verge of this trade reaction and that it is but a short time until we must witness it. If we are to follow precedents, pessimistic people are going to be disappointed, for an examination of the record of the first eight months of the year reveals a most satisfactory condition of our foreign trade—a condition which, as we say, taken as a precedent argues more than words for our future prosperity. From statistics compiled at the Agricultural Department at Washington, it is shown that in the last eight months there has been an increase of $248,551,812, as compared with the like period of 1904. Of this great increase, $145,409,150 was in exports and $103,142,662 in imports. Exports of agricultural products show a gain of $63,117,245 and manufactured articles $53,288,236. In imports the greatest increase is reported in crude articles used in manufacturing, amounting to $49,576,054, while the luxuries exceeded in value those imported in the like period of 1904 by $16,307,226, and manufactured articles increased $14,335,746, and partly manufactured articles increased $13,158,026.

For the month of August the exports show an increase of $25,459,282 compared with those for the same month last year, and the imports an increase of $8,154,897.

Statistics for September are not at hand. But advance bulletins are indicative of even greater increase in our export trade than that given for August. It is this healthy trade showing which most encourages us to believe we are to witness a very satisfactory year to come. For this let us all be glad.

* * *

Eating Up Our Sheep.—According to Consul Williams, of Cardiff, Wales, the world is eating up its sheep. He says that during the past three decades the decrease in the world's number of sheep has been astonishing. Three principal causes are said to be responsible for this remarkable condition. The causes mentioned are: First, people are afraid of such diseases as tuberculosis, trichina and pleuro-pneumonia, hence an increase in mutton consumption; second, the high price of beef during recent years has forced many to turn to mutton; and third, the increase in our city population and the financial prosperity that we have had has caused those fond of mutton to become financially able to gratify their appetites for this kind of meat.

* * *

Senator Allison on Rates.—Senator W. B. Allison is without doubt the foremost man in the Senate of the United States. His views are always sought by the leading lawmakers of Congress and by the public. He does not often talk for publication, but what he does say may be regarded as reflecting the sentiment of his colleagues. In an interview, last week he stated that it was very likely, providing of couse something did not occur in the meantime to prevent, that the Senate would immediately take up the question of railroad rate legislation. The commitee in charge of the matter will report to the Senate ten days after the session begins.

Senator Allison believes that, while the committee has many views concerning the fixing of railroad rates, the differences will be composed so as to result in an effective measure and one which will conform to President Roosevelt's ideas. Senator Allison points to the fact that, inasmuch as the subject has no political flavor, an agreement may be more readily reached through the absence of party feeling.

The bill which passed the house at the last session of congress was a compromise between its conflicting features. When this bill comes up for discussion in the Senate Senator Allison believes that it will be given all the time necessary and that, in view of the unlimited debate in the upper house, a suitable measure will be evolved.

Senator Allison credits the lack on rate legislation at the last session of congress to the short time allowed discussion on the measure. He declared the importance of the general question could not be over-estimated. He said that whatever congress may do at its session this winter additional provisions and amendments will be required from time to time, as the power of congress to deal with this question is undisputed and its duty universally conceded.

* * *

What the Farmers are Doing—There are between ten and eleven million farmers on the 6,000,000 farms in the country and they form the back bone of the wealth and prosperity of the United States. More than to any other one factor do we owe the tillers of the soil homage for the high place which this nation holds in the world today.

Secretary Wilson well says: "What the farmer, in his own modest, but indefatiguable way, has done for the country in the past 20 years, would take a volume—not a paragraph—to tell." It was his toil and brains that have made our exports so large and has kept the balance of trade in our favor.

At the close of the great war England held the most of our government bonds, and it was foreign investors who took most of our railroad and municipal bonds, making us a great debtor nation, and it was Europe which received in interest much of the results of our toil; but the American farmer has changed all this, and it was the meat, bread, cotton, etc., which he produced that have wiped out most of those debts, and while doing it he has fed the hungry people of the nations beyond the sea.

During the last 20 years over thirteen billions of dollars' worth of products, raised by the sweat and toil of American farmers, have gone across the waters to foreign markets. And while he has been doing this for foreign lands, he has helped build up our domestic industries, our educational institutions and our natural resources, until in every department of human endeavor we stand forth the wonder and admiration of the world.

He has not only done this in the line of production, but he devoted much of his time, money and energy in improving his surroundings, improving his live stock, improving his grain and methods of farming and the raising and feeding of live stock. He has not during this time kept his face turned to the earth, but has looked up to the heavens above him and has realized that he had a greater mission to perform in the world than simply to make money. He has realized that he is a potential factor in making the world better and greater, and from the farms have gone a steady stream of boys and girls to our colleges and universities, where they have gone to become prepared to take up the burdens of life, and whether mingling with the roaring stream of political, commercial, or professional life, or returning to the quiet pursuits of agricultural life, they have reflected honor on the old farm home from which they sprang and where they learned their first lessons of industry, honesty and trutafulness.

In the great social and industrial upheavals which are now almost threatening the stability of our national existence, it is the stability and conservatism of the farmers which are the hope of the lovers of the race. Working close to God and with Him in the broad fields, in the sunlight and pure air, they stand unmoved amidst the unrest which is now seen on every hand, and with a trust in the right they know that the world is ever moving onward and upward to better things.

So it is not only what the farmer produces from the soil that makes him a mighty factor in the world, but what he is, what he thinks and what he does, are the factors that make him great.

THE COOLIE PROBLEM.

Editor Cultivator: Does a man benefit or promote agricultural interests in a pure virgin country after he reclaims it and with much self-sacrifice makes it habitable, as is the case in Imperial Valley, when he favors the introduction of Asiatics?

Give us please a few statements and comparisons of other localities, where the Japanese and Chinese have been given an opportunity to establish themselves, and what has been the result?—F. H., Brawley, Cal:

The problem of coolie labor has been, and is, a vexing one. From a purely economic standpoint it is to be doubted whether the country is benefitted by this class of laborers or not.

The Chinese as a rule, take away every dollar they make, over and above a scanty living, and return it to China. The Japanese are more homogenious, they live better and spend more money for social and personal enjoyment. But from the standpoint of citizenship neither race has shown itself to be builders of a country. It is true, in cities like San Francisco and Los Angeles, there are certain Chinese and Japs too, who buy property, but they are exceptions to the rule. From the broad point of view, neither class has shown any ability to build up country or town. We have been compelled to resort to this class of labor because our American bred people will not do the work which the Coolie class does. On the Pacific Coast especially is this the case. We can not hire American nor German, nor Irish laborers for the class of work needed. So it becomes a matter of necessity to take Coolie and Jap labor. As a general proposition it is true we believe, that no special ability has been shown by either of the races spoken of to improve a community nor to advance its educational, social or material interests. Comparisons can not be made satisfactorily, for there are no well developed instances of social or material development from which to draw comparisons.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURAL.

Probably 75 cars of oranges will be the output from the Placer district this year.

Considerable alarm is being created by the continued scarcity of fruit cars for the Pajaro valley apple crop.

Nearly 1000 carloads of fruits have been shipped from Vacaville this season, a heavy gain over the shipments of 1904.

Fruit growers in Yolo county have petitioned the Supervisors to appoint a Board of Horticultural Commissioners for that county.

There are now planted in Fresno county about 125,000 acres of grape vines, over 80 per cent of which produces grapes used in the making of raisins.

Some of the grapes in Sonoma county are showing a very heavy per cent of sugar, going as high as twenty-three per cent. Zinfandels are bringing $20 with the premium on Petit Bouchet.

Three carloads of Mission grapes have just been shipped from Farmersville to a north end winery and it is estimated that fully nine more carloads of the same product will follow this season.

A Santa Rosa dispatch says that the Sonoma wines of last year are selling at about 5 cents a gallon above the prices for corresponding wines a year ago, and that this year's vintage will be a little smaller than that of last year.

In some sections of Fresno county a fungoid disease, or the so-called peach blight, reduced the peach crop, but a liberal use of the Bordeaux mixture at proper times corrects this trouble, which will be reduced to a minimum in the future.

The California Winery at Sacramento, which is purchasing a great many grapes, uses wooden tanks for their transportation. The grapes are dumped from boxes into these tanks. The result is a great saving in boxes and all the juice is preserved.

This season's crop of apples in Monterey county is uniform in size, excellent in quality, and is coloring nicely. Apples are packed and shipped from the following points in the county: Aromas, 3 packing houses; Vega, 1; Pajaro, 1; and Castroville, 2.

A company has been formed and will soon be incorporated, consisting of stockholders from Porterville, Lindsay, Sanger and Fresno, to build and equip a packing house at Sanger for the packing and shipping of citrus fruits through the Tulare County Citrus Fruit Exchange.

One of the features of the next Fruit Growers' Convention will be a session devoted to the consideration of pear blight. It will be led by a paper by Prof. M. B. Waite, of Washington, D. C., illustrated with stereoptican views, and a practical demonstration in fighting it will be given.

Very few know the extent of fruit shipments from the Placer county section; 1902 was a large crop, and 1624 carloads were sent from Newcastle alone. It is said that in the month of June this year, (1905) the express shipments from this office were the third largest on the coast.

The fruit shipments from Placer county for this season are practically over, only a few loads of grapes yet to go. As estimated from fruit house reports, the output this year aggregates 2868 cars, nearly one-half of this amount going from Newcastle and the balance from Loomis, Penryn, Auburn, Colfax and Roseville.

There will be a special session—two if it can be arranged—for the benefit of the Horticultural Commissioners at the next Fruit Growers' Convention, which will be held at Santa Rosa, December 5th to 8th. These annual meetings give the Horticultural Commissioners the best opportunity of broadening their ideas and improving their work, and should be attended by every commissioner in the State.

Bro. Rogers of the Boulder Creek Mountain Echo, boasts of an apple of the Bismark variety over four inches in diameter and weighing 20 ounces, having been left at his office. By moving the cylinder press and knocking out a partition, room was made for the monster apple, and it is now on exhibition as an awful example of what the climate and soil can do in that neck o' the woods.—Los Gatos Mail.

The Watsonville Pajaronian says that about 90 per cent of the dried prune crop of Pajaro valley is in the bins. As to quality the product is without question the finest in the history of the valley, and the output is considerably larger than was anticipated earlier in the season. A couple of weeks ago prunes were in demand at good prices, but during the past few days the market has experienced a slump.

The shipment of wine grapes from Placer county has not been as large as usual this year, owing partly to a slight shortage of crop but principally because the new winery at Roseville has consumed a large share of the local crop. This winery has stimulated the planting of more wine grapes by contracting to pay $15 per ton for the next fifteen years. The Newcastle cannery has been running to its full capacity this season.

J. L. Nagle of the California Fruit Exchange, will install one of the Sprague car cooling plants at Newcastle before the next fruit season opens, such as was in operation at Loomis this season. The experiment of shipping fruit in cars cooled under this system was eminently successful and the plan is likely to be quite generally adopted next season. Fruit that was perfectly ripe was shipped to Boston, arrived in good condition and brought fine prices.

Very good, is the report from Placer county on returns for all kinds of fruits this year. As an example, one peach orchard of 40 acres this season rented for $1500, and the renter netted above that over $6000. Figures of another grower at Newcastle for six years, 1898 and 1903 inclusive, from 40 acres, show an average return of over $8000 per year. Newcastle has ten shipping houses. Few growers are consigning their fruit as there is a good cash market for all fruit packed and delivered to these houses. Loomis has five shipping houses, Penryn three, Colfax four and Auburn and Roseville one each.

AGRICULTURE.

Lincoln and Roseville each shipped between 4000 and 5000 tons of grain, and also about 2000 tons of hay.

Up at Jersey Island, in the San Joaquin, are about 300 acres planted to celery, which if a good crop, should yield about 100 carloads.

The Bellingham (Wash.) Herald says that San Francisco buyers are offering $23 per ton for oats grown in that vicinity, but the farmers are holding for $25.

A large field fire on the Tait ranch seven miles from Red Bluff, which commenced burning Sunday afternoon, has destroyed over 700 acres of stubble feed and about three miles of fencing.

Reports from the river districts near Marysville, where the bean harvest is now in progress, are to the effect that the crop will average much below the normal. The average probably will reach one-fifth less than usual.

An Oregon exchange says that hop-growers throughout the Williamette Valley have agreed not to sell under 15 cents. The local banks in the various hop-growing districts have decided to stand by the growers on this proposition, and no sales under 15 cents a pound are looked for within the next sixty days.

James Seehy, agent for "Block of Santa Clara," is packing 75 carloads of Pajaro Valley apples for shipment to Eastern and European markets. In Covent Garden market, which supplies London, England, with fruit and vegetables, the name of Block on a package is accepted as a guarantee of the quality of the contents.

There have been as many as ten and twelve bean threshing outfits at work around Camarillo in Ventura County, and the work has been done up in a hurry. The crop has been unusually good at Camarillo. Many of the farmers have had as high as 23 to 25 sacks to the acre. Prices have ranged from $3 to $3.52 1-2 cents percental.

Arrangements are being made for beet growing contracts in the Chino district, for 1906, with an advance per ton. The minimum price will be $3.50 per ton, which will be paid for 11 per cent beets For each additional percentage of sugar above 11 per cent. there will be paid 25 cents per ton additional up to and including 15 per cent., making 15 per cent, beets pay $4.50 per ton. Above 15 per cent. for each additional per cent of sugar 30 cts per ton will be paid. On this schedule 16 per cent. beets will pay $4.80 per ton; 17 per cent., $5.10; 18 per cent., $5.40; 19 per cent., 5.70, etc. It is estimated on the percentages of the past years that this will be an average increase of 35 cents a ton on all beets raised for this factory.

LIVE STOCK.

A carload of light oil has been ordered from Orcutt by County Veterinarian, G. F. Faulkner for dipping cattle to eradicate Texas tick in this County.—San Luis Obispo Breeze.

The poultry raisers in the Todd school district, Sonoma County, have had to organize for protection against chicken thieves. They have created a fund to use in the prosecution of these midnight prowlers.

The goat industry is increasing in the foothill districts of Tulare county. With the wool selling at 40 cents a pound and a market growing for young goats among butchers, the industry should be profitable.

Sixteen race horses from Spreckels' Napa Stock Farm were shipped on the steamer St. Helena Saturday night for San Francisco on their way to Los Angeles, where they will participate in the coming races at Ascot Park course.

Advance turkey buyers are visiting many sections in the northern part of the State and soliciting Thanksgiving and Christmas trade at 23 cents per pound delivered at the local depot, and are advancing one-half of the purchase price.

Seventeen and one-half cents was the highest price offered for wool during the sale of the fall clip by the wool growers around Marysville. Throughout the sale the Marysville Woolen Mills continued to be the best bidder up to the end of the sale.

Henry Miller, the venerable member of the firm of Miller & Lux, whose name is synonymous with the cattle industry of the west, paid Reno, Nevada, his first visit in a number of years last Wednesday, and incidentally closed a deal for the purchase of the Linderman range and cattle in Surprise Valley, for a variously estimated price from $75,000 to $100,000.

MISCELLANEOUS.

The Haynes winery, near Los Gatos, was partially destroyed by fire; estimated loss, $10,000.

The Woman's Club of Mountain View, is to give an entertainment in the near future to raise money which they desire to donate to the park fund.

The San Benito County Improvement Club is offering three prizes of $5, $3, and $2, for the three best poultry pictures brought for a special poultry folder they are preparing to issue.

San Jose has caught the improvement fever. An election is to be held to vote on bonding the city for $100,000 to improve Alum Rock Park. A second election will probably be held to provide for sewers and the extension of the city limits.

The dam at the intake of the Power Development Company's tunnel, just below the Edison Company's camp No. 1, in the Kern river canyon is completed, and the entire flow of Kern river, consisting of nearly 300 feet is now running through the power company's tunnel.

SACRAMENTO, October 17.—Surveyor-General Victor H. Woods states that by a presidential proclamation the Lake Tahoe forest reserve has been extended to nearly 1,000,000 acres. The reserve will now cover the watersheds of the south, middle and north forks of the American river, and also the Truckee and Tahoe basins as far as Nevada. The establishment of the Shasta reserve has now been made to include five great watersheds in Northern California, containing tracts in Shasta, Trinity and Siskiyou Counties, comprising more than 1,000,000 acres.

C. H. SESSIONS, ASSOCIATE EDITOR

CRAVING OF HOGS.

In his excellent book, "Feeds and Feeding," Prof. W. A. Henry says of the unnatural appetites developed by hogs in close confinement and the means for satisfying same:

"Every stockman that has kept pigs in confinement has observed their strange craving for seemingly unnatural substances—sand rock, soft brick, mortar, rotten wood, charcoal, soft coal, ashes, soap suds and many other articles greedily devoured when offered. Such articles lie outside the range of nutritive substances, and we are puzzled to know why they should be so eagerly consumed. In the wild state the hog ranges through the woods and open tracts, living upon small animals, larvae and vegetation generally. This material is of such character and is gathered in such a manner that some of the soil is swallowed with it. With rings in its nose to prevent rooting while in the pasture, confined on board floors during the fattening period, and given feeds containing little ash, the pig's life is passed under unnatural conditions. Another cause for this craving may be the intestinal worms, which are checked or destroyed by some of the substances consumed. Unsatisfactory or incomplete as such explanations may be, the fact remains that the pig seeks out these unnatural substances and greedily consumes them.

"Ashes, either from wood or coal, will always be in place in the feeding pen, and even in the feed lot. It is surprising how much of these will be consumed by a bunch of pigs. Feeding trials show that pigs when confined to an exclusive corn diet are greatly benefited by ashes, this substance causing the feed to be more effective and adding to the strength of the bones—the latter result being due probably to the lime in the ashes. Bone meal is another substance useful for strengthening the bones of pigs. By saving the droppings, substantially all the value of this high grade fertilizer may be secured for field and garden after it has served its purpose with the pigs."

DAIRYING IN THE IMPERIAL VALLEY.

Editor Cultivator: Perhaps a few words from one of the older settlers in this "Great Imperial Valley" may be of interest to some of your readers. It is very amusing, though sometimes aggravating to residents here to read the oftimes false and nearly always misleading statements in regard to the overflow of the Colorado River into the lower basin called the "Salton sink" and now known as the "Salton Sea." Uninformed people do not know that nearly all the good portion of this great valley is situated upon a mesa or table land from 150 to 350 feet above the Salton Sea, and is in no more danger of being submerged or washed away than is Los Angeles by the Pacific Ocean. A few settlers along the two river channels leading from the Colorado River to the basin, have had their land overflowed, but little crop was in the way of the water, and but small damage resulted. The water has mostly subsided and the Colorado River will soon be under entire control, and a repetition of the overflow of last spring will be impossible after the work planned and now being done by the Southern Pacific Railroad is completed.

Many improvements are contemplated and much progress is being made all over the valley. Perhaps the one most interesting to Southern California dairymen, and one which dairymen here hope and expect to see realized ere long, is a plan by which we can pasteurize and condense our milk so that we can put it on the market all over Southen California cheaper than it can be produced anywhere on the Coast. Our feed here does not cost over one-fourth what it costs the dairymen on the coast, and many times it is nearer one-eighth. Several capitalists have been investigating the proposition and this is bound to be one of the greatest dairy sections on the Pacific Coast; it is only a question of time when our hopes will be realized. The Jerseys are looking better than ever before. No grain or hay has to be fed here. All fat, while yearlings look like two-year-olds. Twelve daughters of Lowland Lad will soon be milking (two already) and they are a wonderfully promising lot.—D. G. Whiting.

THE DAIRY STEER.

Dairy cows have for centuries been bred and trained for large consumption and assimilation of feed. They are relatively larger feeders and producers than the beef breeds. Loretta D., the champion cow at the St. Louis dairy cow demonstration, consumed daily 25.34 pounds of digestible matter per 1000 pounds live weight, while the average capacity of the beef breeds is only about 13 pounds. She yielded 6.69 pounds of milk solids daily, or 1 pound to 3.4 pounds of nutriment consumed. Add to the milk solids yielded the daily gain in weight, her daily product during the demonstration was equivalent to a gain in weight of 10 pounds per day. This, as the Iowa Homestead avers, shows what wonderful powers of feeding and assimilation have been developed in the high type dairy cow. That she transmits both her feeding capacity and assimilating powers to her male progeny is becoming apparent in feeding experiments with dairy steers.

CHANCE FOR AMERICAN DAIRIES.

Consul Moe, of Dublin, Ireland, sends the following information which, if prompt action be taken, may prove profitable to United States dairy interests:

If the report eminating from London be correct, our exporters of butter should take notice that an excellent field presents itself to them to extend their business by the introduction of American butter in the markets of the United Kingdom. This market is by no means to be disregarded, and if we can gain an introduction of our butter at this seasonable time it may mean the capture of it from the Danish manufacturers, who at present virtually control it. It is generally believed that a large part of the Danish product has its origin in Finland and Russia, being repacked and prepared for the British market in Denmark. If but-

BERKSHIRE BOARS, All Ages
T. WAITE, PERKINS, CAL.

24 YEARS WEAR NO REPAIRS
SEPARATOR FACTS
43 YEARS WEAR 75¢ REPAIRS

Just facts—that's all you want. Facts can't hurt you nor Tubular Cream Separators. Facts prove Tubulars outwear all other makes five to ten times over.

On August 2d, 1904, we started a No. 9 hand driven Dairy Tubular, rated capacity 900 lbs. per hour, on the hardest test a separator was ever put to—an endurance test to last until the wearing parts give way. This Tubular has now run 50 hours a week for 43 weeks—and is still running. Every week of this test is equal to a year's service in a ten cow dairy. No other separator made could stand such a test.

24 Years' Work—No Repairs		43 Years' Work—75c Repairs	
Hours run	1,200	Hours run	2,150
Pounds separated	1,080,000	Pounds separated	1,935,000
Turns of crank	8,155,760	Turns of crank	5,652,070
Turns of bowl	1,152,000,000	Turns of bowl	1,864,000,000
Oil used	3 quarts	Oil used	5¾ quarts
Time oiling	About 4 min.	Time oiling	About 7 min.
Time adjusting	None	Time adjusting	10 min.
Repairs	None	Repairs	75 cents

After 24 weeks, the balls in the frictionless bearing supporting the bowl showed wear. This was natural, for each had rolled over 32,000 miles. Renewing balls cost only 75 cents and ten minutes adjusting, yet made this Tubular as good as new. All Tubulars are equally durable. Catalogue P-260 tells about them. Write for it today.

CLIFFORD'S ANTI LUMP JAW

Lump Jaw can be cured. We mean exactly what we say—there are no "ifs" or "buts" about it. Our firm's name and good reputation are far too precious for us to risk them by misrepresentation. We do not ask you to take any chances in purchasing **"Clifford's Anti Lump Jaw"**—our guarantee of "no cure, your money back" goes with every bottle. We sell either direct or through agents. Price $2.00 per bottle, postpaid.

Our **Hog Cholera Remedy is guaranteed to cure.** Send $1 00 for sample package, full directions enclosed, prepaid, that will check the disease in 12 or more hogs.

Inventors and sole proprietors of Clifford's Medicated Nest Egg. Will kill all vermin. Our **Chicken Cholera and Roup Remedy** will cure all diseases that the feathered fowl is heir to.

ter can be profitably sent from Siberia and other remote districts there is no reason why the product should not come from the United States under the circumstances of direct and speedy transportation possibilities and neat and cleanly packing. An Irish press dispatch dated London, August 2, 1905, runs as follows:

"In the present stringent condition of the butter trade a great stress is laid on telegraphic advices received today from Riga as to strike outbreak at that port, where about 10,000 casks of Russian and Siberian butter are waiting to be shipped to this side. This week's arrivals will, of course, not be affected, but possibly those for next and at least the following week. Should the labor disturbances be of a protracted character in that quarter the outlook of the butter market may become increasingly serious. General supplies, especially from the continental sources, have been so much curtailed to this market, owing to the drought there, that there is at present little or no prospect of relief in sight, while Irish butter is also scarce and the Australian season practically over. Fairly large quantities were lately received from Canada, which helped matters somewhat, but there is no mistaking the abnormal shortage, which has been reflected in values up to a point never reached during the hot season for over twenty years. A further advance under the circumstances can only be expected. Exceedingly high prices were cabled from Canada today."

Last year 1432 tons of butter were imported into Ireland at the port of Dublin alone.

TO FATTEN STEERS QUICKLY.

The Illinois Experiment Station has just issued a bulletin on "Methods of Preparing Corn, Clover and Alfalfa hay for Fattening Steers." The results of the work are stated in 30 conclusions from which we select a few of greatest interest to feeders in general but especially in the northern and central portions of California, where corn is combined with alfalfa to finish off steers.

Silage ranks with ear corn, corn meal and corn and cob meal in its ability to make rapid gains on fattening cattle.

In this test more rapid gains were secured with whole than with shelled corn and equally as good as with meal.

The feeding of a nitrogenous concentrate to supplement corn undoubtedly stimulates the appetite and increases the capacity of the steer for consuming to advantage large quantities of concentrates. Hence this system of feeding is to be recommended where a quick finish is desired.

The presence of the cob in ground corn does not appear to materially increase the efficiency of corn for beef production or for combined beef and pork production under conditions prevailing in this test. Whether or not the cattle feeder should use corn meal or corn and cob meal is largely a matter of convenience, what roughage is used, how the corn part of the ration is supplemented with other concentrates, and perhaps the season during which it is used.

A given amount of corn and cob meal did not produce any more beef and considerably less beef and pork combined than did the ear corn.

Corn meal proved much more efficient for beef production than shelled corn, while for combined beef and pork production, they appear to be about equally efficient.

This test indicates that the supplementing of corn with nitrogenous concentrates used in this instance increases the efficiency of corn and clover hay for beef production.

The chaffing of hay and mingling it with the concentrates in the form of meals did not add materially to their efficiency for beef production, although by this system of feeding there is less likelihood of getting the steers off feed or of scouring.

The amount of gain made by hogs following steers appears to be largely regulated by the amount of undigested corn in the droppings of the steers in an available form for the hogs to recover; therefore, larger gains are made by hogs following steers fed corn only than when it is supplemented with oil meal and gluten meal, thus rendering it more efficient for beef production.

Where enough pigs are provided to consume undigested feed in the droppings of steers it requires fully twice as many where corn is fed whole as it does where meal is fed to the steers.

The results of this experiment are so striking that it appears that the grinding of corn for feeding choice two year old steers during the winter season is not warranted. The profits of feeding ear corn are fully twice as large as those secured by feeding corn meal or corn and cob meal.

The feeding of silage in moderate quantities is not necessarily conducive to heavy shrinkage in shipping or small percentages of dressed beef.

Many who advocate the feeding of ear corn to cattle if hogs follow, advocate the feeding of meal if for any reason it seems desirable to eliminate the hog. The results of this experiment do not warrant such a conclusion. After eliminating the hog from the cattle feeding operations here presented the feeding of broken ear corn was followed with larger profits than the feeding of meal.

While the results of this experiment show that it does not pay to grind corn for winter feeding it should not be assumed that it does not pay to grind corn for cattle that are being fattened in summer on grass.

CURING ALFALFA HAY.

The method employed, or rather the lack of method, by farmers in California, in curing hay, has created a great deal of unfavorable comment by persons from the East. It has also been the topic of criticism by purchasers who keep town and city horses and cows and therefore must buy hay to feed their stock.

Recently the Dairy and Produce Review, of California, contained a very sensible article on the difference between curing hay properly so that it makes a desirable animal food, and simply drying it. What led to the article was the observation of a large consumer of alfalfa in the San Francisco market to the effect that he would not purchase alfalfa hay from a certain section because it was nothing but a mass of woody stems. The farmers who grew it allowed it to stand until it was too old before cutting, and then they let it lie open to the sunshine until it was so dry that the leaves nearly all rattled off. He said, in effect, that they did not know enough to cut alfalfa at the right stage and cure it properly. For that reason he did not want their hay at any price.

Hoards Dairyman takes up the subject and proceeds to say some very pertinent things about the right way to cure alfalfa hay. "It will be remembered," says Hoard's Dairyman, "that we always urged the curing of alfalfa in 100 pound cocks, cutting it as soon as the first blossoms begin to appear, and raking it into windrows as soon as it will handle well on the rake and cocking it up at once, letting as little sunshine get to it as possible. There is a great difference between cured hay in its feeding value, and sun dried hay. When cured in the cock and covered with a hay cap it cures slowly and goes through the sweating process that makes it much safer to put in the mow or stack and besides leaves the hay bright green in color and very palatable to the cattle. This process also saves all the leaves, which are the richest portion of the plant.

We might add that all varieties of hay, clover, timothy and red top, are much more valuable as hay if cut early and cured in the cock and under hay saps the same as alfalfa. What is needed is to induce a slow process of curing as opposed to a quick process of drying.

Many farmers have provided themselves with hay loaders to save labor in the field. Then they leave the grass as long as they dare so that it will dry quickly. In all this they have but one thought, that of doing the work as quickly and with the least labor possible. No thought is given to the feeding value of the stuff they call hay. On that score they are strongly oblivious, seeing only the question of labor.

The real objective point in the production of hay for every dairy farmer should be the securing of the same at its highest milk producing value.

We have often heard the observation, and we think it is true, that too few farmers understand how to produce hay at its best quality. Of course they cannot help bad weather, but every farmer can provide himself with cotton cloth hay caps and cure his hay in cocks, thus reducing the effects of bad weather to a minimum.

There is one view of the economy of alfalfa hay that is not often thought of. That is, the production of a large amount of the most valuable food on a comparatively small area of ground. This season we have put fully 170 tons of first-class hay into our barns from about 35 acres of meadow. To have produced that amount of timothy or red top would have required 85 acres of land as the yield usually goes, to say nothing of the fact that every ton of alfalfa will produce as much milk as 3½ tons of the timothy. But to retain its full feeding value, it must be cut at the right stage and cured slowly in cocks, well secured against storm by hay caps."

* * *

This subject of curing hay, not only as it refers to alfalfa, but to oats and wheat and barley, is a vital one to the stock interests of this State.

The present method is one of drying, not curing, and the hay we get is in many instances not worth anything for feed. It is allowed to stay on the ground in the hot sun and the damp of nights until every particle of strength is taken from it. It is filled with dust, rust and microbes, and damages horses by creating diseases in the stomach which are most pernicious. If common sense were used;

if hay were cured, not dried to death, it would be worth thribble what it now is for feed. We must begin to cure our hay by some rule of reason if we are going to get out of it the best there is in it.

LIVE STOCK INDUSTRY.

Writing of the future of the live stock industry, Prof. Mumford of Columbia, Mo., says: The International Live Stock Show to be held in Chicago Dec. 2d to 9th, will do much to strengthen the stock men in fixing a higher standard of excellence in breeding.

"The International Live Stock Exposition is the greatest live stock educational institution in America. It is the one place where the best specimens of the various breeds of horses, cattle, sheep and swine may be seen. To the man who is interested in the production of market animals, this show affords the greatest opportunity available to study the very highest types. Here he can see the animals on foot and later on the carcases on the hooks. This is something which every feeder should see and study.

THE SILO.

E. E. Moore, Esq.,

Dear Sir: I was interested in reading your article in the Cultivator on Silos. I have never used silage and would like to ask how many acres of corn should one plant to fill a Silo 20 by 14 and 20 feet deep. Would it be an advantage to have it 3 or 4 feet in the ground? Does the studding require cross pins at the top to prevent the silo from spreading.—H. M. S., Riverside.

Editor Cultivator: Enclosed letter I answer through your columns. I had some cuts of my corn and silos in the Cultivator last year showing corn 16 to 18 feet high. I filled my 75 ton silo from 3 acres. This was an exceptionally fine crop grown on a light, sandy loam, planted at exactly the right time and irrigated just as it was coming into tassel. It is impossible to get ideal conditions in corn growing owing to the difference in the seasons, but one can usually grow from 8 to 15 tons of corn per acre. I am always very careful in the preparation of the soil, having it fine and clean of trash. Then just as the corn begins to appear through the soil harrow with a sloping tooth harrow. When about 6 inches high cultivate with a fine tooth cultivator, then again as soon as 18 inches high with a five-tooth, three-inch blade cultivator. If the season be good your corn will need no more work except a good hoeing when waist high, 'til you get ready to irrigate. Just before irrigating I take a large single shovel plow and furrow out so the water runs down each row. Now your corn is eight feet high and forms a perfect shade; turn on your water and see it grow. It will shoot up eight feet in a month. If you desire you can cultivate with the five tooth cultivator again and your crop is made. Of course this method of cultivation is best adapted to the light, sandy loam soils around Compton, other soils may need different methods. But all places and conditions will require that your crop be kept clean and well watered. I used to plant my silage double row, but experience teaches me that a greater tonnage and better corn can be grown by planting single rows or 39 inches apart and drilled in the row. I should think 6 acres cared as above would be abundant to fill a 20 by 14 silo. It would do no harm to have it 3 or 4 feet in ground provided there is a good drainage to surface around silo or cement the pit to a level with the ground. I always brace the top well as I have had several of my silos blow over.—Very truly, E. E. Moore.

SOME JERSEY PRIZE WINNERS.

Clarion Girl, 161,289 stood eighteenth in order of merit in the Jersey herd at the St. Louis Exposition.

Her standing as a diary animal will be better illustrated when it is stated that the eighteenth Jersey at St. Louis equalled in production the average of the best five Jerseys at the Columbian Exposition. The St. Louis Jersey herd was of remarkably even merit. It did not present one or two phenomenal "gushers," the rest being nowhere. Twenty-one cows in the herd averaged over two pounds of butter a day for 120 days.

The nineteenth Jersey in order of merit both as an economical milk and butter producer was Dela S., of Eau Claire. The above cow averaged over two pounds of butter per day for 120 days, at the end of which she was over six months in milk, returning a daily average net profit as a butter cow of 28 3-4 cents per day, and as a milk cow a daily profit of 41 cents. Moreover, her milk contained more butter-fat at the close of the test than at its beginning, the last week's milk containing 12.257 pounds fat, against 11.775 pounds for the first week. Her owner, Mr. E. E. Stevens, kept record of her milk yield after her return home from St. Louis, and he reports that in the year beginning April 24, 1904, she produced 10,650 pounds of milk. Assuming that the percentage of fat for this whole period would not average any more than it did during the official test (viz. 4.2 per cent.), even then this quantity of milk would contain 447.3 pounds of fat, equivalent to 526 pounds 11 ounces butter containing 85 per cent. fat, a year's record that would put Dela S. into the Register of Merit of the A. J. C. C., if authenticated in accordance with the rule. Such is the quality of the Jersey that stood nineteenth in the herd at the St. Louis Diary Demonstration.

Bloomfield Conan, 163,281, was the twentieth in order of merit in the St. Louis Jersey herd as an economical butter-producer, and twenty-first as a milk-producer. With a much smaller yield of milk, she approached closely to the cow immediately preceding her as a butter-yielder, averaging but one one-hundredth of a pound less butter per day. Like all her herd mates, she proved a persistent milker, giving, on the average, under four pounds less milk per day at the end of the test than at its start, after having been nearly seven months in milk. She is a "rich" cow, and in the last week of the test her milk contained more butter-fat than it did in the first. Evidently she is valuable dairy cow of good constitution, regularly consuming her rations and performing her day's work steadily, without hitch or setback.

REGULAR SERVICE BEST.

Editor Cultivator: In order to have dairy cows come in at a certain time, would a dairy man run chances of getting his cows with calf by letting them go by a few heats?—W. A. M. Tulare.

As a rule it is not safe to let cows run past their natural time for service. They may not come in heat again for some time. We have known instances where the cow became very irregular by letting her skip the regular service time.

ITCH.

Editor Cultivator: My horse has, what appears to be the itch. He rubs his tail on the stump until he wears the hair off, he also wears the mane by rubbing until his neck is sore. Has he chicken lice?

As a rule horses are not troubled with vermin although when poultry get into the barn and roost their lice will get onto the horses. The itching at the tail and at the roots of the mane with horses is generally due to over-feeding, lack of exercise and incomplete grooming, more especially the latter and the remedy is to cut out the grain for a time, exercise the animal daily and see that it is properly cleaned with curry comb, brush and cloths doing the work twice or three times daily as long as one owns a horse. To cool the blood give the horse two tablespoonfuls of glauber salts, dissolved in his drinking water, twice daily. As an outward application wash the mane and tail three times a week with a 1-50 solution of coal tar dip.

HOG CHOLERA.

Editor Cultivator: Please tell me what is the matter with my hogs. For a few days past some of them have been dying. They begin by coughing, they seem to have dysentery and in a day or two die. What is the matter and how shall I treat them?—R. M. G., Ukiah.

Your hogs have cholera, from your description of the manner in which they act and die. With all dispatch disinfect the feeding floors, troughs, hog house and their immediate surroundings daily with a water solution of a tar disinfectant two to four per cent.) If this cannot be done remove the hogs and build temporary quarters.

Feed a light, sloppy diet of shorts, bran, etc.

Do not leave water and slop in the troughs for the hogs to wallow in.

Copper sulfate can be dissolved in the drinking water and slop in the proportion of four ounces to the barrel.

Separate the ailing hogs from the herd as soon as symptoms are seen.

The dead hogs should be burned, or buried and their bodies covered with lime.

We lost in fifteen years raising about 200 hogs from cholera. As soon as the importance of disinfecting the quarters, feeding troughs, and use of sulfate copper was learned, the disease was reduced to a minimum.

ALFALFA FOR COWS.

Editor Cultivator: Readers of the Cultivator in this locality interested in dairying would like information through your columns of the relative value of alfalfa for milk production used as pasture or as hay. Also of smallest cream separator manufactured.—G. R. S., Redlands.

It is not usually considered best to pasture alfalfa with cattle. There is always some danger of bloat, and close pasturing injures the stand of alfalfa. Alfalfa hay that has been properly cured is worth as much as any other hay of equal weight, and when fed with a moderate amount of grain is considered to be much the best as a milk producer. Alfalfa cut green and fed when partially wilted is one of the best dairy feeds available and there seems to be litle or no danger of bloat when fed in that condition.

We do not know that any experiments have been made to determine the exact relative value of alfalfa hay and green alfalfa for milk production.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

A SIDE SHOW AT PORTLAND.

The Lewis and Clark Exhibition which has just closed has been a notable and interesting event for the Pacific Coast—I was unfortunately not able to attend the poultry show as I left before it took place, but had the pleasure of seeing Mr. Homer Davenport's fine exhibit (a side show) of pheasants, jungle fowl, peacocks, wild geese and ducks, of all descriptions, which are, or have been, bred from specimens imported regardless of cost at his farm in New Jersey.

There were twenty-three varieties of pheasants, all very beautiful in plumage and from many different climes. The gorgeous Impeyan pheasants from the Hymalaya Mountains were I think the most beautiful. Kipling describes this pheasant, sayiug, "He will start at a great height and fly out over a precipice, closing his wings, will drop like a ball of burnished gold for hundreds of feet, then opening his powerful wings will sail for a mile." They become so tame as to run at full winged liberty about Mr. Davenport's home, he has had one for more than two years, tamer than a chicken. He bought the first that ever came to America and has had the first hatch in captivity here.

The peacock pheasant was another exceedingly beautiful bird with feathers covered with small peacock eyes. These birds are from the hills of Assam and Burmah. They frequent thick jungles and are little known, being more often heard than seen. The males have two or three spurs on each leg, whence their beautiful name "Polyplectron," meaning "many spurs." These birds have bred in captivity and in the London Zoological gardens, the two eggs they lay were placed under a bantam hen, and when they hatched the two chicks kept behind their foster mother. The bantam hen did not understand this evidently, for she kicked them over whenever she scratched for insects. Finally a brood was raised by the peacock pheasant herself, who was observed to spread her tail as a shelter for her chicks, which followed her beneath it, only running forward when she found some food for them, and soon retreating under their curious natural umbrella.

Another interesting fact in the habits of this beautiful little pheasant is the display of the male's plumage. He lifts the wing farthest away from his hen, and spreads his tail on the same slant of that wing so that it is possible for her to see all of his beauty at once.

There were many other beautiful specimens of pheasants, two of which were natives of Japan, and one from Northern Chiua, these greatly interested me not only from their beauty but because coming from cold climates they are easily acclimated to the Pacific Coast and even to England and Scotland.

* * *

Amongst the most interesting of Mr. Davenport's valuable collection were the Red Jungle fowl, the Gallus Gallus called also Gallus Baukiva, as from this fowl came our poultry. This particular bird must have been domesticated very early, probably in Burmah, as the Burmese bird is found easier to tame than the Indiau, from Eastern Asia. It appears to have passed to Europe through Persia, the Greeks calling it the Persiau bird.

The ancients, both Greeks and Romans, had a high opinion of the fowl when they did get it. The Romaus, we know, recognized several distinct breeds at the beginning of the Christian era, including one with five toes, possibly the ancestor of the red Dorking.

The Red Jungle fowl greatly resembles the Brown Leghorn in appearance, but the female of this pen only lays nine eggs before wanting to set, so would scarcely be considered profitable for a twentieth century poultry farm.

The wild fowl of this species which is really the ancestor of the Leghorn, does not average over thirty eggs per year, whilst the ordinary farmers' hen lays about a hundred and fifty eggs, the "bred to lay" hen comes up to two hundred and over. This shows what breeding and feeding will do.

I have not time or space to describe all the fowls in this valuable and beautiful exhibit for there were more rare birds from remote points of the globe than it has ever been my good fortune to see together, some of them the only known birds of their species in captivity.

* * *

I cannot, however, close without meutioning the Red Dorkiugs. Some ceuturies ago careful research was made by the poultry fanciers of Europe and Asia to find what the first known breed of poultry was. They knew before beginning their search that the Malays had domesticated the Red Jungle fowl many years B. C., but a long period elapsed between that time and when the first known breeds began to appear. The Silver Grey Dorking was well known in Europe, although the English people did not know where it came from. Examining records in Rome, they found that Julius Caesar, speaking one night at a banquet, referring to his favorite poultry, said, "Give me the red bird, with the white legs and five toes," and then they were at a loss to know what he meant, as at that time the Red Dorking had not been discovered in England, but it was later found where it had been bred for generations in one family by the name of Hamlin, and then it came about that all other Dorkings had descended from this one fine breed of poultry, and that this Red Dorking was brought to England by the Romans. A test of the flesh proved that Caesar was right, that no finer table fowl in the world can be found than the Red Dorking. They are now very rare, and the pair in this exhibit is the first that has ever been brought to America.

I believe this whole exhibit was valued at over $20,000 and as there were sixty-five varieties, not counting about twenty different ducks and waterfowl, I have no doubt of the value.

BOILED POTATOES FOR CHICKS.

Editor Cultivator: Please tell me are potatoes boiled and used in mash injurious to feed chicks?—G. H. B., Stony Point.

It is not best to feed too much starch to young chicks. Potatoes contain starch to a large degree. Older chickens will stand more, of course, than little ones. Fed in moderate quantity however, once or twice a week in mash, boiled potatoes ought not to be injurious to any extent.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultrymen who have used these machines have supreme confidence in their ability to hatch and brood. Hence their ever increasing popularity. Winners of the GOLD MEDAL at the St. Louis World's Fair for greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1604.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commiesion, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A FILCHER, Commissioner.

And Now Comes New Reward for Merit:

Read the following telegram received from the Lewis & Clark Exposition at Portland:

"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clark Exposition."

BREEDING TO INCREASE EGG PRODUCTION.

In the year 1898 the Maine Experiment Station began an experiment, says the Homestead, to ascertain if an increased egg production could be obtained by a series of breeding from the best egg-producing stock. The stock consisted of Barred Plymouth Rocks which had been bred by the same breeder for twenty or more years, and the experiment was carried on by the aid of trap nests to indicate the hens that were doing the best work. At the beginning of the experiment the hens laid an average of 120 eggs per year.

Each year the best hens were mated with unrelated cockerels from hens laying not less than 200 eggs. The experiment has not yet closed, but the average has been brought up to 240 eggs per year. All the females now being carried in the experiment are tested hens that have laid from 160 to 251 eggs per year. The pullets put in each year are from hens that have laid not less than 150 eggs per year. All the mothers of pullets had fathers and grandfathers that had 200-egg producing mothers.

The bulletin issued by the Maine Experiment Station shows the stock to be strong and vigorous, and but few of the chicks are lost in hatching. Inbreeding is avoided. Nothing closer than first cousins being used in the breeding experiments. Line breeding is followed, the matings now being only with distantly related birds. These breeding investigations have now been in progress six years, the first year being consumed in testing the pullets to be selected for the experiment. The second year the cockerels were from hens with good records as layers.

As before stated, the average of the lot of hens in the beginning was 120 eggs per year. Three years ago the average was 150 eggs. The last two years, with great setbacks in management, and not the fault of the stock, the average has fallen to 131½ eggs. During the time of this experiment, it should be borne in mind that a number of eggs were laid on the floors of the houses and no record could be made, since none but the eggs laid in the trap nests were considered.

The housing, treatment and food have been as nearly alike as it is possible to provide, and there appears to be reasons for assuming that the increase in the yield of the flocks has been the result of breeding practices. The plan of treatment has been along the line of common every-day treatment, such as would be found in any well managed poultry yard.

THE CARE OF YOUNG DUCKS.

Young ducks seem to be able to eat at any and all times. They are the first up in the morning, ready for their meals, and the last to stop feeding. We would not deny that they will feed during the night. We should not suppose, however, that food ought to be before the ducklings at all times. Feeding at regular intervals, and then not more than they will eat up clean, is a far better plan. Food should not be allowed to lie about until it becomes sour, as it is liable to do very quickly in hot weather. The only exception we have made usually, is with the night meal, which is furnished in greater quantity than the ducklings will eat, so that they can come back during the night, or very early in the morning (before we get up) and get the balance. There is never anything left in the troughs in the morning, and the birds are ready for another meal. A writer says a mixture of barley meal with middlings and a little bran or ground oats or corn meal is useful in bringing ducklings up quickly, and a small quantity of tallow scraps which have been broken into pieces and boiled for two or three hours should be added to the meal. We believe in mixing more nitrogenous materials with the food for ducklings, especially blood meal and animal meal, or cut green bone if we can get the bones to cut. The same writer also recommends young nettles boiled, and either given chopped up very finely, or the water strained off and poured over the soft food. "This helps the young birds to feather and keeps them in health. The meal must be given in a stiff, crumbly paste, so that it can be eaten without sticking to the beaks. Water to drink must be provided, both before and after meals. They must also have plenty of gritty sand * * * for digestion." Ducklings will eat great quantities of green stuff, lettuce, beet tops, spinach wastes, cabbage, onion tops, etc.

Ducks are very profitable to raise and becoming more so, as their flesh resemble that of wild birds to a larger degree than chickens. They are therefore very popular with hotel and cafe owners.

HOW TO "RAISE CHICKENS AND A GARDEN, TOO."

The proper feeding of fowls confined in yards the greater portion of the year, and which cannot be allowed their liberty by reason of garden, lawn, shrubbery, etc., is a matter which has taxed the ingenuity of the poultry keeper for many years, says J. D. Stevens in the Reliable Poultry Journal. The bewildering array of poultry "foods" advertised in all the poultry journals throughout the country, which according to the statements of their manufacturers, contain all the necessary elements required by the fowls for their best development, best laying, best fattening, best moulting, etc., respectively, are no doubt good, but, like the numerous infants' foods advertised, they do not contain all the elements necessary for the best health and development.

Fowls which have free range over orchards and fields do not need any of these foods. They will be able as a rule to gather all that is necessary for their best development. But fowls which are kept confined in yards during the summer months, have not this opportunity to properly balance their ration and in order to keep them in a thriving and healthy condition, we must endeavor to supply them with those things which they would obtain if given their liberty. To do this requires considerable forethought, planning and labor, and, in feeding and experimenting with the multitudinous foods above mentioned, as we are all apt to do in an endeavor to get the greatest revenue possible from our fowls, we are apt to overlook one very important element in the diet of our flock, viz.: green food.

* * *

This green food, or vegetable food, is just as necessary to the fowls as the grain or meat ration; in fact, during the winter and early spring when fertile eggs are needed, it is absolu-

tely essential that they have, regularly, a good supply of green food. Steamed clover or alfalfa leaves are a good substitute, but these can not take the place of the fresh, succulent leaves of the lettuce, cabbage, etc., or the juicy root of the mangel-wurzels, and if you want the eggs to run high in fertility (and of course you do during the season above mentioned) you must give your fowls the freshly grown leaves of such vegetables as they will eat.

For very early spring food we have nothing better than lettuce. The seed of this plant is perfectly hardy and can be sown in the fall. If it is lightly mulched, the seed will lie dormant during the winter and will start immediately upon the first warm days of spring, thereby being available for food several weeks sooner than that which is sown in the spring.

* * *

Another good green food for the winter is the cabbage. It makes an excellent food and we feed them in conjunction with the mangel-wurzel. The hens do not relish them, however, as they do the latter.

We also feed, in the mash, cut alfalfa or clover leaves, as these are rich in protein, and therefore, good egg-producing food, and if you are unable to supply the cabbage or mangel-wurzels, the alfalfa and clover is the best substitute you can find. But raise the mangel-wurzels if you can. One trial will convince you that you can scarcely do without them.

Not only is this green food necessary to the adult fowls, but brooder chicks, which are confined in yards, should also have their daily ration of green stuff. We have found nothing better for chicks than lettuce, as the leaves are very tender and if a bunch is fastened up where they can pick it, they will dispose of it in a very short time. They should have it every day, particularly if they are confined in runs. This vegetable is easily grown and by planting the seed a few weeks apart in the spring, a succession of fresh green food can be had all the summer. It helps the chicks digest their grain ration, thereby keeping them healthy and active, and is just as necessary to their growth as the heavier foods. It also adds bulk to the ration and consequently saves the necessity of feeding a higher-priced food, thereby cutting down the cost and adding to the profit.

Try the different "foods" if you wish to; some of them are excellent for the purpose for which they are intended, and the most of them are like the old lady's medicine—they will do no harm even if they do no good—but in your experiments with them, do not forget that all-important necessity to the health and growth of your flock—green food.

Under the penalty of incurring the editor's displeasure by making this article too long for convenience, we nevertheless wish to speak of one more matter which, although it might be made the subject of another article, yet is so closely connected with this question of green food that it may well be combined under the same head. We refer to the poultryman's garden.

* * *

We often hear it said, "You cannot raise chickens and a garden, too." This, under ordinary circumstances, is doubtless true. But here again, with the exercise of a little forethought and planning, and with scarcely any outlay of money, the obstacle can be overcome and the poultryman can have a good garden. It is only necessary to protect the garden for a few weeks in the spring when the young vegetables are just coming up, at which time the chicks do the most damage. And where one looks to his poultry for his living, and not to his garden, it is much better to fence his garden away from the poultry than to fence his poultry away from the garden. In other words, protect your garden so the chicks cannot damage it, and let them have their liberty. Here is our scheme:

* * *

Our vegetable garden is a plot of ground approximately five rods square, situated just north of our dwelling, the driveway to the barn running between the garden and the house grounds. Around this garden plot we set posts, nailing to them at the ground a foot wide board. From the board to the top of the posts we have stretched such pieces of wire as we have happened to have; some of it being four feet, and some being two feet wide, and in the latter case, we have stretched one above the other, fastening the edges together, making it four feet. This gives us a five foot fence, which is plenty high enough for all purposes. A wide gate admits horse and wagon when we wish to manure the ground for spring planting.

As soon as our brooder chicks are well feathered, we release them from the runs and allow them liberty of the ten acres. The foot wide board sitting close to the ground prevents them from getting under into the garden, and they are by that time too large to jump through the meshes of the wire, and after trying it a few times they give it up.

By this method we are able, not only to grow the lettuce, etc., required for them while in the runs, but are also able to have an abundance of all kinds of fresh vegetables for our own use during the early summer. As soon as everything is well up, say by the first of July, we let the chicks have the liberty of the garden also. The only vegetable they attack is the lettuce and this is by this time so large and thrifty that what little they eat does not hurt. They spend most of their time hunting bugs and worms and thus prove more of a benefit than a nuisance. Besides all this, they have their liberty to roam where they please and are much more healthy and vigorous than they would be if constantly confined in yards. You can raise chickens and a garden, too, by adopting this plan, and both yourself and your chicks will profit thereby.

Clip both wings of a hen and she will still fly over the garden fence. Clip only one wing and she cannot do so—it makes her go lop-sided when she flies and she cannot get far. Usually two or three hens in every flock, no matter what the breed, will not respect fences.

When mites are plentiful they drive away lice, and when a chick is free from mites, lice are liable to return. You cannot sit down and let them fight it out, for neither pest is a desirable adjunct to fowls. You must keep wide awake and watchful in either case.

Kerosene is no more effective than some other remedies, but is more easily applied than most. We apply kerosene to our perches by means of a machine oil can. If the stream is too large, divide it by a wooden plug. Move rapidly, also. Kerosene emulsion, or soapsuds and kerosene, is excellent for scaly leg.

The greater the number of chicks raised, the fewer bugs each chick will get off the range and the more bone or meat should be fed.

If fowls show an inclination to change roosting places it is good evidence that insects infest the old roosts.

Corn meal should not be fed raw to chicks, because it is liable to sour in the crop and make trouble.

THE ADVICE CAME HOME TO ROOST.

The president of one of the prominent railway corporations in America was making a stirring address to an audience of young men, and dwelt with particular emphasis on the necessity of making a good appearance.

"When you are looking for work," he said, " be careful that you are presentable. If you have only twenty-four dollars in the world, spend twenty for a suit of clothes, three dollars and fifty cents for a pair of shoes, and fifty cents for a hair-cut and shave. Then walk up to the job, wherever it may be, and ask for it like a man."

This advice was greeted with great applause and the railway president sat down amid a storm of cheers.

The very next morning a dapper-looking young fellow walked into the outer office of the orator, and handing a note to the clerk, said, "Please give this to the president."

The note read: "I have paid twenty dollars for a suit, three dollars and fifty cents for a pair of boots, and fifty cents for a hair-cut and shave. I have walked from Harlem, and I would like a job as conductor on your road."

It is needless to say that he got the job.—Baltimore Methodist.

FOR A POPCORN PARTY.

A novel feature at a recent popcorn party consisted of dainty little square-shaped bowls made from crepe paper of various colors, the shape being formed by gathering up the corners with a few stitches; inside was placed one of stiff writing paper. These bowls were set on pretty plates covered with dainty Japanese napkins. By the side of each lay a ragged-edged card on which some question relative to corn had been written. In the center of the table was large dish, which I suspect to have been a common pan, covered on the inside and out with plainted crepe paper. This was filled with delicious popcorn, which was discussed with much satisfaction while the questions were being answered. The corn was shelled, popped and salted by the guests themselves, half a dozen corn poppers being provided and a rare bed of coals in the big old-fashioned fireplace.

CHANCE TO LOSE HER.

They were about to go for a sail on the lake.

"Shall we—er—take your chaperon with us?" queried the young man.

"Will there be any danger?" she asked.

"Well, the boat might capsize," replied the youth.

"Then let us take her along by all means," said the fair damsel.—Chicago News.

Queries and Suggestions

BLUE GUM SEED.

Editor Cultivator: Will you qlease tell me when to gather and how to plant blue gum seed.—J. C. Santa Ana.

You may plant blue gums now, either in a bed or, as the nurserymen do, in seed trays or flats. They are best controlled in the latter receptacles. The seed may be sown now: not later. In saving seed gather the capsules before they open and put in the sun. You must wait for seed until it "shells out."

WITCH GRASS IN ALFALFA.

Editor Cultivator: I have a field of old alfalfa that is pretty well run out with devil grass. I can illy afford to allow it to run fallow for a year, is there any crop I can profitably raise on it, that will get it in good shape to reseed a year from this coming Feb.? The ground is rather heavy, running to a stiff red clay in spots. It raises fine crops of hay where it is sufficiently soaked, but does not stand a light irrigation.

Also would nitrogen culture help a new reseeding?

I also have about two acres of one year old seeding that caught fine but next to the ditch the devil grass has choked the alfalfa badly. The plants are there but can not grow. Would winter harrowing help the difficulty? —A. S.

As corn does well on your land we would advise that crop for a year, with good clean cultivation. On your young crop, disc harrowing during winter would help the alfalfa and somewhat discourage the grass. Nitrogen culture would probably not aid reseeding but would benefit the plants after they are growing.

BOUNDARY LINES.

Editor Cultivator: There is a very perplexing question puzzling me, so I send it to you to solve, if you will, through your valuable paper.

If parties who own land joining should have some difference over a few feet of land. Say the firts party was there a year or so, and then the second party bought the land joining him, and then had his land surveyed, and found out that the first party had several feet of land he had bought and gave him notice to vacate and he would not do so.

How would he recover the land that belonged to him?

Also will a survey made by a competent surveyor, not a county surveyor hold good; also would he have to have his corner stakes recorded?—Mrs. M. B. V.

A dispute as to boundaries is to be determined by survey, and any competent, reputable surveyor is, in the eyes of the law, on an equally good footing with the county surveyor. The county surveyor secures a little prestige by his election to do county jobs, but a jury or judge might determine, from the character of the evidence that he was an inferior and incompetent surveyor.

There being a plain and probably an honest difference between the parties as to the line of division, it remains for the owners to each employ a surveyor to represent their respective interests in a new survey, where the error made by some former surveyor can be readily corrected. There is no room for difference when a competent survey is made. If, however, there should be a difference in the results arrived by two apparently competent surveyors, it will be readily seen that only a trial of the case in court could determine which one of the surveyors was in error, where a preponderance of competent testimony would settle the issue.

Recovery of land can be made by notice of trespass and afterward by suit, if trespass exists.

It is not necessary to record the corner stakes, as the surveyors notes indicate where they were set.

The best and safest rule in all such differences is to consult a reliable attorney.

PLANTS AND SEEDS WANTED.

Editor Cultivator: 1. Please give me a list of the herbaceous perennials and what time to plant them.

2. Also name of some rapidly growing vine for veranda. 3. Is there a pink climbing rose vine that will grow well in this locality, we have an altitude of 2000 feet above sea level.

4. What time should carnation plants be set out for early blooming? 5. Also rose bushes, raised from slips? 6. Can the tall growing nasturtiums be planted any time—with irrigation.—Very truly yours, Mrs. F. A. R., Alpine.

1. Ageratum, anemone, aster, begonia, boltonia, candytuft, canna, Canterbury bells, chrysanthemum, coreopsis, cuphea, daisy, dahlia, day lily, evening primrose, foxglove, forget-me-not, fuchsia, gaillardia, geranium, golden rod, grasses, heliotrope, (dwarf), heuchera, hibuscus, (herbaceous), hollyhock, hunnemannia, iris, larkspur, lavender, linum, lobelia, lupine, nierembergia, pansy, petunia, phlox, pink, poppy, primrose, rudbeckia, salvia, snapdragon, statice, stevia, stocks, sweet alyssum, sweet william, verbena, violet, wall flower . Plant now.

2. Australian pea; or the Madeira vine. Either one is very fast in growth; so is the perennial morning glory. For an an annual nothing grows faster than the hop. 3. Dorothy Perkins, Empress of India (splendid), or climbing Malmaison are three pinks. Crimson Rambler is a very deep rose color. 4. Now. 5. Anytime after rains commence. 6. Yes, but frost will catch them in many districts; they are tender.

INSECTS ON ORANGE TREES.

Editor Cutivator: There is some kind of insect eating the young growth on my orange trees. It is very much like lice, of a yellowish color. It makes its first appearance in the tender shoots, crawling and eating on the top side of the leaves, causing them to curl up, after a time it develops wings and disappears. The leaves partially straighten out, but the tree has a ragged apearance. The same thing occurs with each growth.

Can you tell me through the medium of your valuable paper the name of the pest and a remedy? Yours truly, C. C. A. Sanger.

The description given in the above letter is not sufficient to determine what insect is attacking the trees. Specimens of the insect should have been enclosed in a phial or box and forwarded with the letter. It can hardly be aphis as they are not active at this time

R. M. Teague, the well-known nursery man reports an insect (unknown to him) attacking the young growth (principally) of the oranges of the northern section. It extracts the chlorophyll or green coloring matter of the leaf, leaving it striped and blotched. The insect also weaves a web. This would seem to indicate that it belongs to the mite or spider family and is probably the same insect referred to above. It may be a newly imported insect or a native species that has suddenly become active. We would recommend the use of the distillate mechanical mixture or distillate emulsion as an experiment. Subscribers who write for information in such ccases as above should forward specimens of the insect.

GARDEN QUERIES.

1. What would you think of the landscape effect of planting our driveway, between which and the lawn are redwoods strips, with Lippia repens to prevent washing, which, as we are on a sloping hillside takes place more or less? There is not enough driveing to injure the growth, and the Lippia would be more restful to the eye than the bare ground and cleaner. We have thought of making a stone gutter on the outer driveway side of the drive but the Lippia idea has just occurred to us.

2. Would not a good covering of Lippia tend to conserve the moisture in the soil? What effect would it have upon the fertility of the soil?

3. What shall I do with my Chinese lily bulbs, which were planted in March and grew thriftily but did not flower and have now "died down."

4. Can you tell me something of enclosed shrub? From a little pot plant set in the open ground, it has made a wonderful growth of several feet during the summer and is now budding at the tips of the long graceful branches.

5. When shall I transplant my double white and single purple violets?—L. S. W., Glendale.

1. The scheme of planting Lippia in the driveway is a very commendable one, nothing could so much aid in giving a "restful" touch to the local landscape.

2. Lippia will aid in the conservation of soil moisture, its draught either of moisture or plant food, is very light.

3. If the bulbs have cured of their "own sweet will," allow them to remain dry one or two months longer and replant.

4. The flowers and leaves sent are from Escallonia rubra, a shrub from South America belonging to the Saxifrage family.

5. Now or in early spring, as you find convenient.

PEAS FOR THE ORCHARD.

Editor Cultivator:—

1. In a recent number of the Cultivator, Professor Cook advised planting peas in the orange groves during September. Our grove has been cultivated every ten days during the summer and the soil is dry for five or more inches below the surface, should peas be planted under such conditions, and how deep?

2. In the July 21st Cultivator under the head of "Clean cultivation or no cultivation," the exhaustion of the soil by long continued clean cultivation was set forth, what would be the desirable method to pursue with no cultivation?

3. Would it not increase the humus and also the friable quality and water containing capacity of soil which has been successively planted for fifteen years to grain, to plough as deeply as possible after the first rain and sow to peas; thereafter they get a good growth and the soil is wet deep enough to plough with a subsoil plough and plant to grain or any desired crop?—L. S. W., Glendale.

1. Peas should not be planted in your orchard until after a thorough irrigation. Under present soil conditions the peas would not sprout until after the first rain. Plant peas three inches deep now, either with drill or by plowing them in.

2. You can only practice "no cultivation" with an unlimited supply of water, and in such a case you should have a cover crop; if you should not provide one, nature would, very quickly.

3. The peas, if growing vigorously will take up so much water and so fast that you would never be able to sub-soil after the first rain, no matter how heavy, until you first gave the land a good irrigation. Otherwise your scheme is all right.

RAISINS AND OLIVES.

Editor Cultivator: Please tell me through your columns how to take care of raisins after they are dried, should they be packed in boxes or sacks and how long must they remain in the sweat-box. Also please tell me how to sulphur almonds and pickle olives.

Thanking you for an early reply, I am, Very truly yours,—Mrs. F. A. R.

Raisins should be put in sweat boxes

and so remain three or four weeks. These boxes should be tight and if raisins are very dry the boxes should be piled directly above each other, to exclude all the air possible; as they dampen up a little some air must be given—watch them closely. If raisins are yet somewhat green, give the air free access for a while. Do not put more than 4 or 5 inches of grapes in each box.

Do not sulphur almonds unless they are very dark colored, and to be marketed, they are better without it In sulphuring they should be sprinkled to make them moist, put in a bin or box with perforated bottom and burn the sulphur beneath, allowing the fumes to go up through the nuts.

The following is the process used by one of our largest olive picklers. Give a lye bath twenty to thirty hours time and strength of solution vary, and are based on experience. Then wash thoroughly and put in a weak brine—four ounces of salt to the gallon. After five days put in another brine—six to one, then seven to one, and on to nine to one. This last is the best applied scalding hot. They may now be canned, put in sealed jars, or left open. The above is merely the formula, for successful olive pickling, experience is the greatest need.

OLIVE CRUSHER.

Editor Cultivator: In the Cultivator of August the 18th, you have a cut of an olive crusher and press. Would you kindly inform me where I could purchase a small outfit for making olive oil as an experiment I have but a few trees of the Mission olive and would like to try on a small scale. —A. J., Santa Barbara.

Write to Toulouse & Delorieux, 618 Commercial street, San Francisco.

MILDEW ON BEANS.

Editor Cultivator: Enclosed you will find some beau leaves. Please tell me what ails them and the remedy. —A. R. G., Tustin.

Leaves are covered with mildew. Nothing can be done to get rid of it in such an advanced stage. Moreover, a bean crop is not worth such a trial. The disease probably could have been prevented if the vines had been sprayed in time but it is doubtful if the crop would pay for the labor and material thus expended. This disease is usually due to unfavorable weather.

LAWN MAKING.

Editor Cultivator: Will you please inform me how to make a blue grass lawn. I have tried twice but failed each time.—Newcomer, Petaluma.

It is rather late to make a lawn now, for the young grass would be "in the milk" just at the time of our usual frosts and even a slight frost would injure the grass in that stage. Better wait now until March. The method given below is for a first class lawn.

Thoroughly work the ground to a good depth and turn under two to four inches of well rotted manure. Cow manure is the best, unless soil is very heavy. After spading, wet down well and let stand till dry enough to work, then tread over every part of it carefully, with your feet close together. On large lawns we resort to the use of rollers, but this mode does not find the small soft spots as well as your feet and sufficient time can be spent on a small lawn to do it in a most thorough manner. This treading will insure you an even surface and no future settling.

Rake the low places full of soil, making the surface just as smooth as possible, for as you leave it so it will remain. See that the surface is pulverized as finely as possible. If the surface is perfectly dry when you wish to sow the seed, give it a light sprinkling and let it remain for an hour or two until it gets over being sticky. The seed should be sown when there is no wind, early or late in the day is best. Begin sowing at the back side, using boards or planks to walk on, for when you surface your ground you must "back-up" in the work and never set foot on the plat again until the first mowing, all sowing, covering, watering, weeding, etc., must be done from boards laid down. After sowing the seed and raking it in gently and not too deep, sow over the surface one half inch or so of well-rotted cow manure, previously sifted through a one-inch mesh, and then give it a good "soaking."

The first watering (and subsequent ones) must be given with care, and the water evenly distributed with a fine spray so as not to wash the seed around or make channels through the manure cover. As soon as the weeds are large enough to pull, get in on your boards and weed. Better have two boards, one to kneel on and the other to keep your toes from digging up the soft and easily disturbed soil. Remember that manures carry lots of seeds of noxious weeds and should be thoroughly rotted or "wet down and turned over several times previous to using. When the grass is tall enough to make the least cutting possible, cut it as often as the growth will allow. Care must be taken to tread very flat-footed for the first two or three mowings or until the grass gets started sufficiently to keep you from tearing up the earth.

By following closely the above directions you will get the best lawn obtainable.

RAPE AS A NURSE CROP.

Editor Cultivator: The query of subscriber and your reply with regard to sowing barley with alfalfa bring to mind a question I asked at the Seaside Institute last year, as to the suitability of rape for a nurse crop for alfalfa. I have since tried the experiment. I did not sow it with alfalfa but by itself. I had seen some in a garden patch in the outskirts of Long Beach but did not know how it would fare with the small attention which would be given it, if sown as a farm crop. The first week in November last year I drilled about one-sixth of an acre, using planet and garden drill. The land had been irrigated about a month previously for the purpose of sowing onions, but did not hold moisture close enough to the surface to suit me.

The land varied from very sandy to slightly alkaline. The seed started first and made the best growth on the best land, but when the cold wet weather of December came it started well all over and by the latter part of January was from 18 inches to 2 feet high.

By the end of March where it had not been fed off it was over 4 feet in height.

The long, broad leaves make a good shade while the single stalk will not crowd out alfalfa as barley does when it starts. Of course it would have to be sown very thinly, about 1 lb. to the acre, I should think. Rape is what I should use if I sow any more alfalfa.

Your reply to Mr. Bell about three weeks ago, included a remark that farmers should reclean their seeds. To do so by hand would be very tedious, while to get machinery to do it with, would cost more than the benefit to be obtained, unless one was sowing very extensively. The dealers could do it more economically if they desired, and the extra price which purchasers would have to pay, would be compensated for, by the fact that they would have to buy less seed. The amount (25 to 30 lbs.) of alfalfa recommended is a great deal too much. I use 12 lbs., and by using a seeder and going over the field lengthwise with one-half the seed and crossing with the other half generally get good results. According to the Encyclopedia Brittanica there are about 12,000 seeds to the ounce almost 200,000 to the pound. Therefore if every seed were fertile and properly sown there would be about 9 plants to every two square feet.

If you sowed five lbs. and allowed 1 lb. for unevenness in sowing another for too deep or too shallow covering there would be 3 lbs. to grow. If the seed was 66 2-3 per cent fertile that would leave 2 lbs. to the acre or 3 plants to the square foot which would make them 4 inches apart, which is about as thick as it could stand when it obtained its growth, consequently if 10 lbs. or 12 is sown that would bring it to 18 or 20 plants to the foot, which ought to satisfy anyone.—C. B., Long Beach.

FLY KILLER.

Editor Cultivator: Can you give me any receipt for fly killer on cows, or to keep them from congregating on screen doors at night.—P. J. M., Palms.

There are a number of insect powders which may be sprinkled or rubbed on cows, but they are no more effective than a thin blanket made of grain sacks and tied around the cow. The latter we have used with good results.

In the fall flies will collect on screen doors and it is difficult to find any thing to clear them, except to brush them down early in the morning, and sweep them up and burn them.

TULARE GRANGE.

The Tulare grange convened in regular session on the 7th. A bountiful lunch was served.

The special committe appointed at a former meeting to report on the conclusion of the Board of Supervisors as to granting a franchise to individuals or incorporations to erect poles and stretch wires for the transmission of electric power, generated on Tulare River, in Tulare County, beyond the county limits, reported that the Board of Supervisors had resolved to grant a franchise for the transmission of this power, but under strict conformity to the law governing such consessions.

Mr. Fred Jacob, of Iowa, being present on the request of the Worthy Master, gave an account of the working of the Mutual Fire Insurance Companies of that State. In 97 counties there are 117 Mutual Fire Insurance companies; they have been in existence many years; between two and three hundreds of millions of risks are on their books, risks are written for five years, no risk is assumed until the company has applications amounting to $100,000; no one risk in excess of $4000 is written; losses are paid by assessment; assessments are made the first of each year; assessments now averaging one and a half mills per dollar per annum, no assessment any year exceeding two mills per dollar. In all the years the company has done business, this has been sufficient to meet every loss; the greatest one loss in Mr. Jacob's company being $2455.50; every loss is promptly paid as soon as adjusted, the company borrowing the money until the annual assessment is collected; local banks loaning the money at 4 to 5 per cent. No money is collected until needed, so no funds are kept on hand to excite the cupidity of weak agents. Expenses are met by a collection of one dollar for every risk written and of one-fourth of one mill on the dollar on the amount of risk.—J. T.

Parties near Springville, Tulare Co. are going to try date growing on a commercial scale.

OCTOBER DAYS.

The goldenrod is burning
  Its yellow torch so bright,
On rocky ledges flaming
  Beneath some barren height.
The asters pale and purple
  Have come to keep their tryst,
To trim the fields and byways
  With gems of amethyst.
The clematis and ivy
  Have dressed the walls of gray,
And golden corn is waving
  Above the pumpkins gay.
October hours are golden
  Her flowers are jewels rare,
Her fruits are rich in nectar,
  She is a goddess fair.
Oh! Crown her queen of Autumn,
  And bid her steps delay,
Ere winter comes as monarch
  To steal her bright array.

—Louise Lewin Matthews.

Playing With Fate

Harry followed the porter into the parlor car, folded up his overcoat, and settled down to read; but he could not fix his attention upon his novel.

The occupant of the opposite seat disturbed him. Apparently she was asleep and unconscious of traveling backward. She was pale and there was a pathetic droop to her lips. The book in her lap was slowly but surely slipping from her unheeding fingers.

Its slow progress troubled Harry. He wished the volume would travel faster and get the threatened catastrophe over with, so that he might attend comfortably to his own reading.

The expected happened at last, however. The owner of the book opened a pair of startled brown eyes and looked straight into harry's interested blue ones.

"Why, Harry!" she exclaimed, flushing from throat to brow. "It is really you? You're not a ghost?"

"Certainly no ghost," said Harry. "To think that I didn't know you, Beatrice! But it's been—let me see, how many years?"

"Don't speak of years; what are you doing in this part of the country?"

"I'm going to Pidgefield to spend Sunday."

"So am I."

Harry did not think it necessary to state that the main purpose of his going was to ask a certain young woman an important question. Perhaps, as things turned out, it was quite as well that he refrained from going into details.

"Do you remember," asked Beatrice, "what good times we used to have in the rose garden."

"We were next-door neighbors then, weren't we? I used to crawl through the hedge on my hands and knees to visit you. What was it we used to play?"

"Supposing. 'S'posin',' we called it then."

"Oh, I remember. You sat on the bench near the beehives, with your lap full of big pink and white roses, and I sat on the ground at your feet. It began like this: 'S'posin' a pirate should come and carry you away—' "

" 'In a great big ship with lateen sails—' "

" 'And a crew of murderous Lascars—' "

" 'And chests full of gold——' "

"Gold, certainly. I'd follow——' "

"Would you, Harry?"

"Of course," said Harry, not noticing that the girls voice had grown tremulous. "S'posin' this is the ship."

"Yes—yes——"

"And we're sailing—sailing——"

"To a far-off country, and the pirate is waiting on the shore——"

Beatrice glanced apprehensively over her shoulder.

"Waiting to seize me and carry me off to his dungeon. Yes, go on. I can see him."

"I'd draw my sword and slay him, and say. 'Fair one, be mine. Come to these arms. I love thee!' "

"O, Harry! You—didn't say it, afterward, when—I used to wonder sometimes."

The girl's face flushed, and then paled suddenly.

"But the pirate didn't come. You didn't need me. If he had, you know ——"

"But I think—I have reason to believe I'll find him waiting at the station. He's a wealthy pirate with chests of gold, and—the family expects it."

"I'll run him through with my broadsword—my umbrella—if you say so."

"No, it's too late. I rather think I shall have to let him carry me off, and yet—s'posin'—s'posin' at the same moment——"

"Norwalk—all change!" the conductor called out lustily.

Harry leaned forward.

"Let me take your bag. You are sure——"

"Look! Just inside the gate."

"Not Anderson, Beatrice? Surely not Anderson, of all men?"

"Yes, Anderson. The pirate, you know."

"Beatrice, s'posin'—oh, Beatrice, let me save you!"

"Do you mean——"

"Yes, everything. Quick! May I save you—now—always? I always meant to, Beatrice."

"Oh, do ,do!" cried the girl, with a lovely color flooding her face, and her eyes dewy with tears of joy.—Emma E. Reis is American Queen.

Caught hugging his best girl, a smart farmer's boy declared he was only embracing an opportunity. And then his sweetheart flashed out that "her name wasn't Ann Opportunity—he knew well enough that it was Editha Madeline Smith! And if he was ashamed of her he could just make himself scarce around there and hunt up his Ann!"

Manners are of more importance than laws, being the foundation stones of civilization.

Simplicity of manner shows the best breeding. Effusiveness and loudness are the stumbling blocks of good manners.

BEAUTIFYING THE HOME.

In this utilitarian age when people are directing their thought to money making alone, the following well made suggestions by Mrs. Creighton in the Farmers' Sentinel, will be found of interest: There are few people who are altogether indifferent to the beauty of their homes, but the majority care more about comfort than beauty, and to many the association of the familiar objects around them with the happy days that are past and the dear ones they have lost, means far more than any intrinsic beauty they may possess. But there is no reason why beauty should be dissociated from comfort, and there is no reason why cherished associations should not add a new beauty to objects already beautiful in themselves, whilst it must be a gain to live amidst surroundings which please and charm the eye and help to keep the mind serene.

It is a mistake to suppose that only the rich can hope to have beautiful things around them, and it is equally a mistake to suppose that there should be a fashion in beauty. Before all things, the home should be an expression of its owners' minds, should speak to us of them. It is a pity that so many homes should only tell us that their owners have utterly conventional minds, and have never troubled to have a taste of their own. Some one was consulting me the other day about the decoration of a new house, and in speaking of some detail of ornament he said: "But will that be the right thing?" To which I could only reply, what could it matter whether it were the right thing, so long that he was sure he liked it? But he remonstrated that it was so difficult to have the courage of one's tastes, and so vexatious after one had decorated one's house to have people coming in and telling one that this or that was not right.

I do not think the real difficulty is having the courage of one's taste, but forming a taste at all, and knowing what one's taste is. Anyone who really admires, and knows his reasons for admiring, will not be shaken because he finds that others do not admire where he does.

Yet we must own that there are many who have no capacity for forming a taste of their own and these need not be ashamed of seeking guidance. It seems a pity that they should be so often willing to be guided by the man in the shop, who tells them what is quite new, or what is most sold, or gives them some other specious reason for getting them to take his particular goods. The knowledge of character shown by the salesman is indeed admirable. He knows when to sympathize with a desire already formed, when to guide a vacillating mind, when to express scorn for the commonplace, when to plead the authority of fashion, and when he may hope to persuade the weak minded to discover that something hitherto unsaleable is just what he has always wanted. But if we have not clear views of our own as to what we like we might at least try to exercise judgment in our choice of those by whom we will be guided.

It is even possible for all to arrive at least at some principles of taste for themselves. Increased faculties of production and communication have multiplied the objects with which we can adorn our homes. We have more things and cheaper things than our forefathers had. Their tables and wardrobes lasted for generations and still adorn many of our homes. The drawing-room and bedroom suites which we buy hardly last a lifetime, and make the homes of our old age often look little better than a shabby hotel. If we care about the beauty of our homes, the first thing we should remember is that we must buy nothing that is not good, and, if possible, beautiful in itself.

Why should we want to have everything at once? It is to possible to live with a few things, and these, if they are carefully chosen, will give all the more delight because they are few, and because they are beautiful. Then there will be always be the pleasure of adding as we can afford it to our treasures, adding only after much thought, much trouble to find exactly what we want, and so getting the fullest possible enjoyment out of each new possession.

In towns, rooms should be as scantily furnished as possible, so as to make it easy to keep them thoroughly clean and fresh. They should suggest sweetness and cleanliness, at least, however simple they are. But of course if there are to be few things, it becomes all the more important that they should be well chosen, that they should speak to us of the tastes, even of the characters of their owners. In a scantily furnished room also the color of the walls, and of the carpets, assume a special importance. The carpet can be well seen, and it is worth while, if possible, to have a really beautiful carpet. Your carpet will probably meet your eyes more often than any other object in your room, and may grow to be almost a friend. A good carpet may live with

When writing advertisers mention Cultivator.

you all your life, and in your old age, still beautiful in its old age, may speak to you of the children who have played on it, and the dear feet which have trodden it.

The decoration of the walls needs also much consideration. Before we bewilder ourselves with books of patterns from the paper hangers, let us try and discover what we really want, and not be guided merely by fashion, which one fears may tell us to have a paper covered with peacocks and poppies, and another year to cover our walls with brown paper. If we happen to possess many pictures or engravings, the decoration of the walls must be decided so as to make a good background to them; if there are few things to hang on the walls some may like the decoration of a well designed paper, and that in most cases a quiet, soothing effect of color is likely to rest us more than a luxuriant growth of scarlet flowers, or a frieze of purple mountains with pine trees standing out against a crimson sky.

The arrangement of our pictures also needs thought. To begin with, they should be hung low enough for us to see them. It is difficult to imagine why it should be so common to hang pictures high above the line of the eyes near the ceiling. The frames should be well made, and suited to the picture. We should not be tempted by the cheap and tawdry frames, which quickly fall to pieces and let in dust behind the glass. We need not speak about the hanging of really fine paintings since few are so fortunate as to possess them, and moreover they may almost be said to hang themselves, as it is impossible to spoil them. But in these days it is possible for almost anyone to have at least a few photographs or engravings of really fine pictures, and the choice of these should reflect the taste of the owner.

A GIRL'S NEED OF COURAGE.

What does the girl who has to make her own way in the world need most? Some say ability, others health, again perseverance. Foolish people say beauty, wise ones character.

All agree that she must have courage. That is what every woman needs, and is what few girls ever get from their early training or from their education.

Physical courage will never be a feminine virtue, as long as high heels, long skirts, corsets and tight sleeves are a part of a woman's clothing.

You can't feel that perfect confidence in your own strength, no matter how fine your physique may be, when your heel is likely to turn any minute and your arms are kept from their natural, broad free movements by confining bands.

A boy learns as soon as he is out of creepers that he is to be a brave man some day and must not cry. The ideal is held before him constantly.

No one tells the little girl not to cry when she is hurt. Courage is taught the boy at every step.

The girl has to learn her own lesson later when it is harder and then without aid.

What every working woman wishes for herself is courage:

Courage to look upward and beyond the narrow limits of every-day work.

Courage to trust again when trust has been betrayed.

Courage to get out of the engulfing rut of things.

Courage to keep on seeing and believing the good in people despite every day's experience.

Courage to fight the destroying sense of loneliness and isolation.

Courage to help others, even where it seems to do no good.

Courage—supreme courage—to keep faith with one' self.

Courage to hold to the knowledge of the Love Divine, which is the source of all courage.

Courage to keep one's ideals and to fight for them if necessary.

Courage to face the facts and keep on smiling.

Courage to pull one's self together after mistakes and begin again.

Courage to forgive where forgiveness will be called weakness.

Courage to bear slights and insults without complaining.

Courage, whatever comes, never to whine.

—Margaret Hubbard Ayer.

A STORY OF STONEWALL JACKSON.

It happened that the writer and another cadet occupied the same room with Major Jackson and another officer of the institute. As we were retiring, the Major said to the officer mentioned. "Captain, what do you do with your watch and purse when spending the night in a hotel?"

"Well," said the Captain, "I have no fixed rule; but ordinarily I put my waistcoat in which I carry them under my pillow."

"I can tell you a much better way than that," said the Major. "I always place my watch in one sock and my purse in the other, and lay them on the floor as if they had been thrown there carelessly. No one would think of looking into a pair of soiled socks for valuables.

We were up betimes next morning—before daybreak, if I recollect aright—and, having breakfasted, started for the wharf to take the boat. We had marched possibly a couple of squares when we were surprised to hear the Major's voice giving, with his peculiar intonation, the command: "Detachment, halt. Place rest." Turning to see what was the matter, we perceived the Major trotting briskly toward the hotel. He soon returned, and marched us to the boat.

Suspecting the cause of the stoppage, I approached him as soon as the boat had started and said:

"Major, I was much struck with your method of concealing your watch and purse last night, and I think I shall adopt it hereafter." A broad smile crept over his face as he replied:

"Well, Mr.——, if you do follow the plan, don't put on clean socks the next morning and forget the soiled ones, as I have done today."—Thomas M. Semmes in the "Century."

FAMILY DEVOTION.

At the close of a lecture in a neighboring town his friends entreated Wendell Phillips not to return to Boston. "The last train has left," they said, "and you will be obliged to take a carriage into the city. It is a sleety November night, cold and rainy, and you have twelve miles of rough riding before you get home." To which he replied, "But at the end of them I shall find Annie Phillips."

This is a beautiful anecdote illustrating his devotion to his invalid wife. —Herald and Presbyter.

LOOKING AHEAD.

Our little people are the life of the Christmas holidays, They begin a long time ahead, to plan for Christmas presents for them they wish to remember, and they lay awake nights turning over in their minds just the things they most desire for themselves. They realize in a wonderful knowing way about the extent of the gifts they may expect and they figure with banker-like minuteness, how much money they will be allowed to expend on older friends. We have in mind a womanly little maiden of about nine summers, who said to her father the other day, "Papa, I know what mama wants for her Christmas present, but I haven't enough money to buy it. Brother and I have each 25 cents, but we need some money, can't you give us what is needed to buy mama this present?"

Papa thought a moment and said. "I will make a bargain with you, daughter, you and brother wash the breakfast and dinner dishes for mama and I will give you the balance needed to buy your present for your mother." The deal was straightway closed and two happy little hearts and four willing little hands are now busy with these household duties.

Right here is a thought, how easy is it to gratify the desires of children and how much of real happiness may we throw into their lives by grasping their suggestions and acceeding to them, and by the way, how much of real practical work can we get out of them by becoming their partners in all laudable little enterprises which while they are small in themselves, small to us, are still big in the minds of the children. This father, by grasping the scope of his little daughter's ambition is giving her happiness and educating her, as well, along the line of household duties.

We make the mistake too often of treating with indifference the behests of our children. We do not enter enough into their lines, we do not become a part of their existence, looking through their eyes, so to speak, out into their world. It is well now and then to turn the hands on the dial of our watch lives back to the time when we were young and to be a child again, just for an hour, that we may study our children in the light we looked at things when we too were boys and girls.

Cookery Recipes

Suet Pudding.—One cup raisins, 1 cup currants, 1 cup finely chopped suet, 1-2 teaspoon cinnamon, 1-2 nutmeg, 1-4 teaspoon allspice, 1-4 teaspoon cloves, pinch of salt, 4 cups flour; mix all together well, and add 1-2 cup brown or granulated sugar, 1-2 cup molasses, 1 cup milk, 1 teaspoon soda, dissolved in 1 tablespoon milk, grated rind and juice of 1 lemon and a well beaten egg. Stir all thoroughly together and steam four hours. Serve with hard sauce—butter and sugar creamed together, and whipped white of egg added, or any sauce preferred.

Oyster Bisque.—A soup relished by those who "do not care for oysters." Heat the proportions of liquid wanted, making it 2-3 of milk and 1-3 of water, with seasoning of butter, salt and pepper to taste; it is best to season lightly, as each person can add seasoning to taste at table; while the liquid is heating, remove all bits of shell from the oysters and chop them fine in the chopping bowl, turn them into the hot milk, add a little thickening of corn starch, let boil about five minutes and serve. A quart of oysters will make "a bisque" nicely flavored for twenty persons.

People who have been tearing out olive trees because they were supposed not to pay, might profit by the experience of Judge Victor Montgomery of Santa Ana. On his Villa Park ranch the Judge has 130 olive trees, covering less than two acres. A few days ago a Los Angeles buyer came down, looked over the crop and offered $500 for it as it stood.

THE BEST
IN THE UNION

The California Limited Log-Book:

March 30, 1905.

My work takes me into all the States of the Union and all the Provinces of Canada. My mileage is from 25'000 to 30,000 annually. I have been on about all the first-class trains of all the first-class lines. All things considered I have never seen anything to equal the California Limited on the Santa Fe.

(Mr.) MARION LAWRENCE,
Toledo, O.
(Gen'l Sec'y International Sunday School Association.)

San Francisco Markets.

Dairy.

San Francisco, October 18, 1905.

Butter buyers were cautious in their operations yesterday, limiting their orders to small parcels to balance immediate requirements, but with supplies relatively light, the general market maintained a firm tone and the quoted prices were well sustained. Offerings of strictly fancy Creamery grades were well cared for, the maximum quotations being easily obtained for the favored marks. Storage Butter held a good buying interest and the prevailing prices were obtained with a marked degree of firmness.

BUTTER—Per lb:

Creamery, fancy 31
Creamery, good to choice ... ..28@30
Dairy, choice ... .Nominal
Store ....Nominal
California storage ... .24@26
Eastern Creamery ....23@26
Eastern, ladle ....20@21

CHEESE—Per lb:

California Creamery, mild, new, extra ....14@14½
California Creamery, mild, new choice ....12@13
Young America ....13½@14½
Eastern ....15 @17

Eggs.

Values for ranch eggs showed no further variance, strictly fancy offerings ruling firm at the maximum quotations, while some easiness was noted in the undergrades because of a slow sale. The call for storage stock was brisk and available supplies were quickly marketed at maintained rates.

EGGS—Per doz:

Ranch, selected large ... .42@42½
Ranch, good to fancy ....37½@40
Store ....Nominal

CITRUS MARKETS

The week shows a gradual cleaning up of old citrus fruit, many Eastern markets being unable to obtain anything like a sufficiency for immediate demands, with New York getting the majority of the shipments. As a consequence prices have remained at a high figure for both oranges and lemons, and shippers still having sound fruit to send are reaping good profits, as the Mexican and Florida new crop is arriving green and selling badly.

New York.

Much deciduous fruit was offered Friday and had a lowering effect on oranges, but the two cars of high grade Valencias that were offered brought satisfactory prices. Some averages were: Shamrock, fy, $7.20; Cambria, st, $5.48; Gem, or, $4.63.

Oranges were quickly taken Monday, the two cars of high grade Valencias selling at record prices. Old Missions were again in the lead, one car grossing $2,927.38, the highest of the year. Old Mission, fy, averaged $8.85; ch, $7.53; Golden Eagle, st, $6.66; Blue Globe, ex fy, $6.15.

Oranges were in good supply Tuesday for this season of the year, three cars being offered, including twenty-eight boxes of "off bloom" navels from Orange, which were of good flavor, and averaged $4.04 per box. Valencias averaged from $3.93 for standard to $7.16 for extra fancy. The lemon market was exceptionally good, extra choice averaging $7.13, while fancy brought $5.70.

Two carloads of Valencias were offered Wednesday, one of Old Missions, averaging $8.78 per box, while the other ran from $5.37 to $6.30.

Chicago.

California oranges were scarce Friday, and Floridas in fair supply. Late Valencias ranged from $4.50 to $6.00. Grapefruit, $5@6. Lemons were in fair demand with light supply. Sound stock, 360s, $5@5.50; 300s, $5.50@6; 400s, $5.50@5.25.

The market Monday was fair with considerable green Floridas on hand. California late Valencias, $5@6; Floridas, ripe, $2.90@3; lemons, $5@6; Messinas, $5@5.25.

Practically no California oranges in the market Tuesday, and late Valencias brought $5@6 per box; lemons, $5@6, as to size and grade.

Very little fruit in the market Wednesday, and that brought from $5 to $6.50, as to quality.

Boston.

The market Friday was bare of oranges, and the one car of late Valencias brought the highest prices of the season, ranging from $2.50 to 7.05 per box, with the supply totally inadequate to the demand.

No oranges or lemons from California were offered here Monday or Tuesday.

One car of Valencias was offered here Wednesday, bringing good prices, $2.75 to $5.95 per box.

Citrus Shipments.

The total shipments to date are 29,468 cars, of which 4336 cars were lemons.

While out Vernon way a few days ago, we dropped in to see Mr. Yarnell. He has a large quantity of seedling walnuts for this year's trade which he told us were not only of good size, but show a most thrifty growth. Of course, as heretofore, Mr. Yarnell will have a full line of deciduous fruits.

At the time of our visit he was busily engaged in making a large number of nursery boxes for several varieties of Eucalypts, which are now in the seed bed ready for transplanting. These he has in large quantities, of the more common blue and red gum sorts, also a very fair number of the ficifolia and others more rare. The ficifolia, by the way, is the variety which has the magnificent scarlet blossoms.

If you are contemplating buying an engine be sure to examine the White & Middleton at Wm. Gregory's 602-606 N. Main St., Los Angeles, or write for circulars and prices. It has many feautures of advantage which are easily shown. Mr. Gregory has the agency for Southern California and Arizona and will be pleased to furnish full information to any one desiring a first class engine. See advertisement in this paper.

Ventura County estimates her bean crop at over 100,000 sacks more than the total yield of 1904.

ORPHANS RECEIVED.

The following named children have been admitted to the Boys' and Girls' Aid Society of South Pasadena, Cal., since the last report:

TROPICAL FRUITS FOR CALIFORNIA.

There are many so-called tropical fruits which may be grown, in favored spots, well toward the northern line of this State. The rapid development of the citrus industry has tended to obscure the importance of this class of fruits, but in many sections the ranchers are experimenting quite generally along these lines and in the near future we expect to see many new home-grown fruits which heretofore have been shipped in from distant parts.

CIRCULATION EXCEEDING 10,600

You You Yours

Your Business to Consider

A ton of Shorts or Bran or Chop Feed contains not much more than 180 pounds of digestible protein; while a ton of COULSON'S EGG FOOD contains over 300 pounds of digestible protein.

Now as "protein" is one of the most valuable parts of the feed for making eggs, you can readily understand that you will get more results from one ton of COULSON'S EGG FOOD than you would from a ton and a half of either shorts, Bran or Chop Feed.

Therefore, it would actually be cheaper for you and prove more profitable for you if you should feed your pullets and laying hens COULSON'S EGG FOOD every day.

Unless a food, however rich in protein, is relished, it loses much of its value.

Therefore, we make COULSON'S EGG FOOD in a condition that fowls will relish it.

They eat it greedily—THEY JUST GO FOR IT—because it tastes good to them and they like it so.

If you should feed only grain and a mash composed only of Shorts, Middlings and Chop Feed, etc., without any extras, in the way of animal foods, your average profit on your entire flock would probably not average over 75c per hen, per year.

If you should mix Beef Scraps, Meat Meal or Meat, etc., with the other feed, the profit might be increased to $1.00 per hen per year. If you should feed the hens COULSON'S EGG FOOD every day, a food that is just right, the hens will earn you a profit averaging from $1.25 to $1.50 per hen, and sometimes more, per year.

Now, if the above is true, and it undoubtedly is, one would do BETTER BY USING COULSON'S EGG FOOD, and save a lot of worry and bother of mixing feed, etc.

(1¾) Tons of Shorts at $25.00 per ton would cost $44.00.
(1¾) Tons of Bran at $24.00 per ton would cost $42.00.

Therefore one ton of EGG FOOD is equal to $44.00 worth of shorts; it is equal to $42.00 worth of Bran, or $45.00 worth of Chop Feed or $50.00 worth of Corn; and it is better because it also keeps the fowls in more active and healthy condition.

COMMENTS:

184 EGGS PER HEN

Henry Graff, a prominent poultryman near Petaluma made a flock of 1400 hens average 184 eggs apiece during the past year.

THAT'S GOING SOME

Considering the large number of hens,—as there are always some hens that are not layers.

They were fed once every day on COULSON'S EGG FOOD.

I have fed your Egg Food for the past three months to my flock of 200 pure-bred Brown Leghorns with the best results. I believe it HELPS THE FERTILITY OF THE EGGS, as I have had a higher percentage of hatches than heretofore, and can cheerfully recommend to all poultrymen.
W. E. MERCER, Ventura, Cal.

This is the first season I have used COULSON'S EGG FOOD and I consider it excellent for the purpose. Since August last I have had MORE THAN DOUBLE THE NUMBER OF EGGS I ever had before from the same number of hens. A. A. HENRY, Rumsey.

I have fed your Egg Food and had good results.
S. M. BUTLER, (Arrowhead Strain B. P. Rocks.)

I find your Egg Food proves to be just what you recommend it to be.
E. M. SHELFORD, Cloverdale, California.

Have been using your feed since last August, 1904, and have never had such a healthy, happy lot of hens before. It carried them safely through the molt without any sickness and they are laying well at present with eggs at 35 cents a dozen.
MRS. E. M. HICKS.

Full particulars of your dealer. If he does not keep COULSON'S FOODS, etc., give us his name and we will tell you where and how to get them, and save you money.

A Sack of Coulson's Egg Food

The World Renowned
COULSON'S EGG FOOD

A Balanced Ration or Mixed Feed for Pullets and Laying Hens

Intelligent Feeding.

Feed the hens Coulson's Balanced Ration Egg Food. You can buy it nearly as cheap as wheat, and it will make the hens lay better than any other food.

A hen is simply an egg-making machine. Feed her properly and she is bound to lay eggs regularly. Feed as a mash one meal a day. Simply wet it up with a little water or skim milk, and it's ready to feed: it saves you time; it's the busy man's friend. Feeding a properly balanced ration the year round will yield double the profits if you feed COULSON'S.

Take the sack of Coulson's Egg Food, dump some of it out in a box—pour some water or skim milk on it. Stir it up so as to make a dry mash, (meaning not too wet), then pour it into the feed troughs for the growing pullets and laying hens. They should be fed COULSON'S one meal every day.

The supreme test of a hen is her Egg-Making Capacity. A good hen should lay about 200 eggs per year, which she will do if fed regularly on COULSON'S EGG FOOD.

Cut out this slip. A handsome needle case free.

Vol. XXV—No. 17 LOS ANGELES, CAL., FRIDAY, OCTOBER 27, 1905 Subscription $1 a Year

The World's Largest Celery Fields

Vast Acreage Once Considered Nearly Worthless Now Among the Most Profitable on the Pacific Coast

Down in Orange County between Santa Ana and the ocean lies the largest, most productive, most profitable celery fields of which any record exists. But a dozen years ago this vast tract was nearly useless, furnishing a scanty crop of stock forage at such seasons as it was dry enough for cattle to roam thereon. For a large part of the year much of it had water standing on or very near the surface.

When it was discovered that wild celery, so common in California was growing all over the tract in unusual luxuriance, it was realized that here was an unusual opportunity. We may say in passing that wild celery differs in no wise from the cultivated sort except the improvement by the enterprising horticulturist. Apium graveolens, the wild plant, has by selection been brought up to its present standard of perfection by many years of careful selection.

When celery of commercial value was first tested on the drier portions of this territory and its wonderful possibilities demonstrated, the problem of reclamation became a serious one. First open ditches were resorted to, but as the area of celery culture extended, under-drainage by tiles became necessary. The last few years has seen train loads of tiles placed beneath the surface and the work still progressing. By the system in vogue the water is absolutely under the control of the growers. When the drains are opened, the lands drain until the water is three or four feet below the surface. When drains are closed the water soon rises to the surface, giving the most effective mode of irrigation ever practised by man. While further drainage will add a few more acres to the celery growing area, the soil suitable for its most successful culture is limited and the future will see little addition to the present acreage. Future development will lie in getting the better returns from the lands already under control.

Celery is first sown in beds—either broadcast or drilled as the grower prefers, beginning the first of April and continuing up to the first of July. Celery sown the first of April will be ready to harvest in November, while that sown in July will not mature until February or March, thereby enabling the growers to ship celery from the first of November to the first of April. About the 15th of June transplanting commences and continues until the 15th of September. The celery plants are pulled out of the beds by laborers who prune the tops and roots properly. The roots should be left about two inches long, and after being pruned are placed in tin pans in about one inch of water. The beds should be well irrigated before drawing the plants, and the ground in which the celery is transplanted should be well worked and moist.

It is set out in trenches made by an implement designed especially for the purpose. Rows are drawn four feet apart, and the plants are set six inches apart in the trenches as soon as they are made. In about two weeks after celery is planted, the dry dirt is crowded away with a most valuable implement made V shape with two steel blades, each three-eighths of an inch thick, six inches wide and four feet long. The implement is six inches wide at the mouth and three feet at the rear, is drawn by two horses and cuts all weeds between the rows, besides pushing the dry dirt from the celery.

AN ORANGE COUNTY CELERY FIELD.
The Finished Product—a Week Before Shipment, Oct. 20th, 1905.

The plants are kept thoroughly cultivated from this period until the time comes for hilling up, which begins about October 15, and continues until the end of the season, as celery is much better when banked only a few weeks prior to marketing. Hilling or banking up the celery is begun by working the dirt gradually to the celery till it is nearly buried.

In about three weeks after the celery is hilled up it is ready for the market.

The roots are cut with a machine made for this purpose and drawn by two horses. The laborers take the celery up in their hands and very carefully break the undesirable leaves off, trim the roots properly and pack it in crates, or tie in bundles of twelve, as may be required. It is then immediately placed on wagons, hauled to the packing house, packed securely in refrigerator cars, and is ready for its eastern journey.

Celery is shipped in crates, 22x24 in. base, which holds six to eight dozen of celery, according to size. An average crate will weigh about 145 pounds, and 160 crates make an average carload. Some Eastern dealers prefer the celery shipped in bulk or on decks built in the car. This is a much cheaper way to ship, and is claimed by some to be just as safe. In shipping in this way, three decks are built in the car, and the celery is tied in bunches of one dozen each and stood upright with roots resting on the decks. By this method three or four hundred dozen more celery can be packed in a car.

Celery is shipped to all the principal cities of the United States and Canada, and carries successfully, especially under refrigeration. All celery is sold f. o. b., none being consigned. It is all handled at present by the California Vegetable Union, who not only control the Orange county output, but that of Central California as well. The latter consists of 300 acres at Jersey Island and the returns are somewhat problematical, as the latter section is not so suitable for celery growing as Smeltzer and vicinity.

Should it develop later in the season that too much celery has been grown for the market, such surplus will be plowed under, as this is a much better plan than to ship the celery and demoralize the market. Plants are in fine condition at the present time, and all these point to a splendid crop for the present season. Shipments began the last week in October and it is expected the season's output will total 2000 carloads. The 1905 acreage is about 3300, as against 3100 for last year.

New sorts are constantly being tried out, and no less than a dozen are under experiment this season. In the earlier days of the industry White Plume was thought the best, but of late the growers have largely discarded that variety for Golden Heart and the latter promises to be the leading sort in the future.

The California Vegetable Union has a leverage on the railroad companies that is a great advantage to the growers. They do not fail to use that leverage in shipping the output. Where stock is damaged the company is able to adjust the damages more satisfactorily than could an individual. Inquiry reveals the fact that special trains of celery have been started from Smeltzer and run through to Chicago and New York without change and on fast time. This special fast service has been of immeasurable value in putting the best celery in the world into the best Eastern markets on quick time and in the very best order. The last annual report also shows that a special representative located at El Paso to examine each car of celery in transit has been of great value, inasmuch as a close tab was kept upon the product while en route, and to see that there was no delay at that point.

The officers of the association state that they have met with much sharp competition from all parts of the United States, and urge upon all growers the urgent need of raising the best product and putting it on the market in good condition. They also urge that all growers stand close together, work hard to one end, that being to improve the product and put it upon the market in good form. Particularly was the point urged to raise the best stock, meanwhile urging all growers to stand close together in the interest of the greatest and most profitable vegetable grown on the continent. The last report reveals the following facts:

That during the season of 1902-3, there were shipped from this locality 1179 carloads of celery; for the season of 1903-4, 1554 cars; and for the past season, 1904-5, 1800 cars. The past season has been the best yet, so far as celery production is concerned, yielding this people over $400,000 clean hard cash in hand.

California Horticulturally

By John Isaac, Sacramento, Cal.

QUARANTINE AGAINST FLORIDA ORANGE STOCK.

With the approval of Governor Pardee, Horticultural Commissioner Cooper has declared a quarantine against any citrus fruit or nursery stock from Florida coming into this state. This is on account of the prevalence of the White fly, (Aleyrodes citri), which is doing much damage in that state. This pest has not yet obtained a foothold in California and if any action on the part of the Horticultural Commissioners can prevent it, it will not for some time, if ever, It is certainly a pest to be dreaded and one which, once introduced, would do inestimable damage to the greatest of our fruit crops. We have a number of species of Aleyrodes common to our state, but these are innocent in comparison with the citri. This family is an interesting one from the fact that it is a sort of connecting link between the scale family and the aphids. In its larval stages it has all the characters of the scales, the great difference being that in its mature form both the males and females are provided with wings, while in the scales the males only are so provided, the females rather degenerating until they are little more than egg receptacles for the next generation. The group has never been properly studied by any of the entomologists, and there is still very much about it that is unknown. Enough is known of this one variety, however, to appreciate the necessity of keeping it out of our orange orchards if we would not have a pest that would prove second only to the cottony cushion scale.

* * *

CALIFORNIA, THE WORLD'S INSTRUCTOR.

The wonderful success achieved in horticulture by our state has resulted in her taking the foremost stand among fruit growing nations of the world and her methods are eagerly studied by other parts of the world in which fruit is or can be grown. South Africa has turned to us for instruction, and has not only sent us students but has taken Californians and put them in charge of orchards, in order that our methods might be established there. The latest visitors who have come here for this purpose are James H. McCall, a member of the Australian parliament for twenty years, and Geronimo L. de Galvez, delegate of the Minister of Agriculture, Industry and Commerce of the Argentine Republic. Both of these gentlemen have been making a thorough investigation into our methods of growing, packing and marketing fruits in the interests of their respective countries.

* * *

CORK OAKS AND CAMPHOR TREES.

Many of our state papers are advocating the planting of groves of cork oaks and camphor trees, stating that the young man who does so will find himself with a competence in his old age. The advice may be good, but it is questionable whether any young man in California will take it. Our California young men are not built that way. They want returns for their labors while they live, and are not content to plant and then watch and wait for years for a problematical income, and then, after waiting an age for a crop, they would have to find some way of harvesting and disposing of it. Camphor and oak may do for the slower and more patient countries where one generation plants that another may gather, but not for California. Just think of a man planting such a crop and waiting for old age to come to enable him to gather it, and should he die before it was ready—for all people do not become old—what a world of fun he would have missed. Better stick to fruit and get the first crop in two to four years and enjoy the income as it comes in.

* * *

THE NEXT FRUIT GROWERS' CONVENTION.

It has now been definitely settled that the next Fruit Growers' Convention is to be held at Santa Rosa, Sonoma County, commencing on Tuesday, December 5th and continuing until the following Friday. Among the more interesting features of the meeting will be the consideration of the pear blight, which has obtained so serious a foothold in the pear orchards of Northern California. Prof. Waite, the expert on this disease of the Department of Agriculture, will come from Washington on that occasion for the purpose of demonstrating methods of fighting this disease and keeping it in check. There will be an entomological day devoted to the consideration of insect pests and their control, in which the County Horticultural Commissioners will discuss various matters connected with their work. Arrangements have already been made for reduced hotel rates, railroad excursion rates for attendants, trips over the electric lines, and various means of entertaining the visiting members. This convention will be one of the most important and interesting ever held, in all the 31 years they have been running.

* * *

EXAGGERATED STATEMENTS.

The tendency of the daily press to sensationalism does much harm, in that it sets standards which it is impossible to reach, and raises hopes which it is impossible to satisfy. I notice in many of the papers that the purple scale is doomed and that it will soon be a thing of the past, and because Compere is now searching for a parasite to prey upon it. The old lady's recipe for cooking a hare is very applicable in these cases. Said she: "First catch your hare, then skin your hare." In this case we hope for an efficient parasite, and are trying to catch it, but have not yet succeeded in this. The fact is that there is a parasite of the purple scale in China. That much we know. We are trying to get it, then we have got to transport it here, and then perhaps it will not do so well here as it does in its native land. There are many contingencies which may arise, and very many obstacles to overcome before we can safely say the purple scale is doomed. We may make this statement in regard to the black scale as safely as in regard to anything, but even here there will be outbreaking of the pest. We cannot even say that the codling moth is doomed. But we can say that we have a parasite which is working on it, and which so far promises well. We can tell better about it in four or five years from now, and it is always safer to tell what we have done than what we are going to do. There is one thing however, which is certain, and that is that there is a check on every form of life. In the insect world this check consists largely of parasitic insects, and it is profitable to search for and introduce this class of insects, even though ninety-nine in a hundred are not satisfactory. An effective check on any one of our troublesome species is of infinite value. Who can compute the value of the Vedalia cardinalis or the Scutellista alone? Every new species brought here will not be successful, and it is to be regretted that exaggerated press reports raise our hopes so high that we are disappointed, as such disappointment often results in a lack of faith and a revulsion of feeling and a good cause suffers.

* * *

END OF THE FRUIT SEASON.

The fresh fruit season is now practically at an end, for while there are still some shipments of Tokay and Cornichon grapes going forward other fruits have stopped. The season has been an especially favorable one for fruit shipping and for the shippers, for while the crop of most varieties has been light, prices have been so high that, even with reduced output, the growers are in advance of most seasons, while the shipments have been the heaviest on record, very far exceeding those of last year, which was the banner year until the present.

GUARD THE FORESTS.

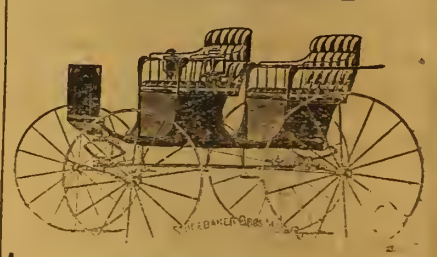
Since California surpasses all other States in the extent, diversity and magnificence of its forests, and in the importance of the varied industries dependent upon them, it has a correspondingly vital interest in forest preservation. That the welfare of every community is dependent upon a cheap and plentiful supply of timber, and that forests are the most effective means of maintaining a regular stream-flow for irrigation and other useful purposes, are recognized principles of public economy. In California their significance is usually great, for the timber products of the State afford a revenue of $15,000,000 annually, besides furnishing employment to many thousands of men and directly benefiting every industry, while the very foundation of agriculture, fruit growing and the value of residence property is the supply of water for irrigation. It is not theory, but a fact well established by bitter experience in this State as well as throughout the world, that forest destruction is felt by every person and interest, and that recovery is slow if not impossible.

While unwise use of the forest resources is responsible for much unnecessary destruction, and there is need for reform along this line as fast as experience and better market conditions permit, the great source of injury is forest fires. The fire question in California is so serious, far-reaching in its bearing upon the welfare of all, as well as on that of those whose lives and property are actually endangered or destroyed, that it is a matter of personal and civic duty for every citizen to give it his attention. While probably all admit that forest fires are undesirable, few realize their annual number and extent. The reported fires are few compared with those which burn unrecorded, smaller, perhaps, in individual importance, but aggregating an immense loss to the State.

To preserve and improve the remaining forest resources for the fullest use, and to protect the indispensible water supply, have been undertaken by the State itself through the creation of a Board of Forestry, the appointment of a State Forester, and legislation against the careless use of fire and encouraging the conservative handling of timber and wood lands. But no successful reform was ever accomplished by legislation alone. If California is to avoid the distress which inevitably follows the loss of timber and water, it must be through the co-operation of her citizens, and this should be freely given for reasons of private interest, public duty and State pride. You can render your community no more valuable service than the use of all your influence toward the enforcement of the Forestry laws and instructions. It will also be highly appreciated if you will assist the State Forester and the fire wardens by reporting violations and by any information or suggestions upon forest matters.

It is not the intent to make the law burdensome. While every reasonable step will be taken to protect the California forests, due allowance will be made for established customs and conditions.

Studebaker Vehicles



Stand Without an Equal

They are constructed throughout of the best material, by skilled workmen in the largest vehicle factory in the world. The wise buggy or wagon buyer will always purchase a

Studebaker

because they last longer and give better service than any other make.
We carry a complete line of the famous

Studebaker

Buggies, Runabouts, Phaetons, Farm Wagons or Harness

You cannot make a mistake in purchasing a

Los Angeles, California

A SUCCESSFUL WOMAN RANCHER.

By Mrs. M. E. Sherman.

In the year 1884 the failing health of my father brought the entire family to California for a permanent residence. Leaving Philadelphia, with its busy social life, and the opportunities of a city, the change to California was a happy one.

My father and mother, believing it best for girls to be independent, gave me some money to use as I thought best. After looking around for an investment, I purchased a section of land five miles from Fresno, intending to sell it again when values increased. The land was raw and unimproved with the exception of ten acres of wine grapes, four acres of old vineyard of mixed varieties and thirty acres set to almond trees.

After a year of wheat planting the spirit of the neighborhood prevailed and a forty-acre muscat vineyard for raisin making was planted. This was steadily added to until there were two hundred acres of muscats. Meanwhile Bartlett pear, olive and peach orchards followed and then a table-grape vineyard. The raisin-grape vineyard afforded sufficient revenue to carry the expenses of the young orchards until they themselves became profit-yielding.

Sending East for books, I took up butter making, and soon found that I had as well to study cows, stables and the cleanliness of the dairy. The alfalfa taste which in some places is noticeable, had to be kept out of the milk as it was impossible to remove it with any means I could command. This taint was conquered, but led into the study of bacteriology as far as making cultures, to find where the control was needed, and of the cultivation of the bacteria essential to high flavor. The knowledge that we had good butter on our table quickly spread among friends and they begged for a roll or two a week.

I was thus carrying on butter making on a small scale with the usual farm outfit when the need came for more money to carry out my larger plans and the surest source of income on the ranch proved to be the dairy. More cows were secured, a small separator and a Babcock test followed. As cows were scarce, two carloads of Arizona nondescripts were purchased, and milking time for the next month or two was a Buffalo Bill show. The dairy proving a success, fifty head of registered Holstein yearlings were brought from the East, and a steam plant with large separator and power churn were added. This was the first alfalfa creamery and won the first gold medal ever given to alfalfa butter. The two hundred cows paid in seven years an average of $51.65 a year per cow.

With the registered cows came the fascinating study of breeding to increase excellence, to build constitution and to eliminate weakness and defects. The success of this study has been shown in the results I attained, for in the third generation came Juliana De Kol, the world's prize milk and butter producing cow, which the California Promotion Committee sent to the Buttermakers' Convention held in Chicago during the World's Fair. Fidessa, a winner at Sacraemnto for several years, and over twenty other cows with records of over twenty pounds of butter per week were bred here on my ranch.

Another success has been attained with table grapes. By careful selection the Emperor has been developed into a heavy bearing vine with large highly colored fruit in magnificent bunches. When these grapes were first shipped from the ranch the packing was done in Fresno, where the large bunches were cut to fit small baskets, eight of which were put into a crate. Their value for table use was almost completely destroyed, so I opened a packing house at the ranch and by laying down the sides of the small baskets managed to pack the bunches uncut. The next season larger baskets were ordered, and all the crate stock was ordered for single crates. Ribbons left from the previous season's raisin pack were used for decoration, and they sold at once for a dollar more a crate than the rest of the pack. Each year we pack with the same care and now after having heard that the large package was often more than a family cared to buy of high-priced fruit, I tried one year sawing some crates in half, thus making a smaller package. This also sold well, so that we try to place in each car seventy-five half crates. The returns from the Emperor vineyard have always been good, ranging from $10,000 to $15,000 a year after freight refrigeration and packing material have been paid for. Like the care of the cows, this has been a most interesting work, for in all life the same laws prevail, and if the grower does not constantly build up the strength and carefully select his vines and trees there will be only a minimum of success. Pedigree is as important in a plant as in an animal. In the vineyard, fertilizing and pruning, spraying and clean cultivation put the vines in the best condition for bearing. Quantity of fruit must give way to quality, for quantity makes pigs' feed, while quality makes money.

My olive orchard also has a pedigree, being only two generations from the trees of an old mission. We had a friend who grew the trees from cuttings from the bearing wood of his own orchard. At four years of age the trees bore a half crop, and have not failed since. The olives are so large and fine that the first two sizes have been sold under a five years' contract for $75 to $80 a ton f. o. b. Fresno. The smaller olives are pickled for local trade and oil is made that sells readily in the East in case lots among private customers.

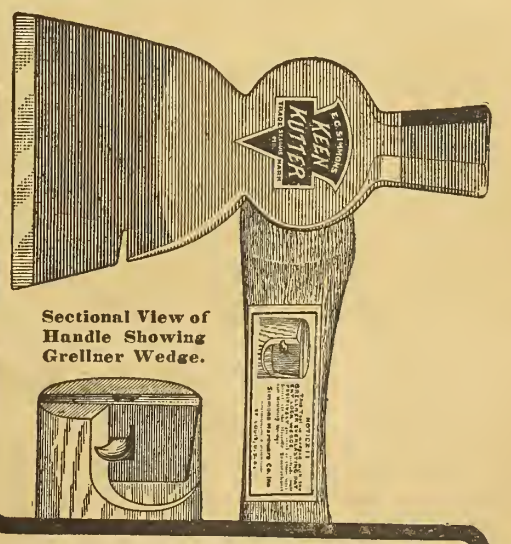
These are successes, yet without a few failures they would be less sweet. The beautiful Bartlett pear orchard, just when at its best, and when the brand had built up a reputation for good packing and prices were increasing, the blight came. Though each winter, in hopes of saving at least a portion the blight was carefully removed under antiseptic conditions, yet each year the trees had more cut off than the summer growth renewed, until only pitiful stumps remained and these were finally cut up for fire wood. The second failure was the peach orchard. It bears well, but "haste made waste" and the trees were foolishly bought instead of being grown and budded to order. They were labeled as Early Crawfords, Mui,rs and Orange Clings. How many varieties of peaches are cultivated I do not know. I feel sure, however, that I have every one of them in the forty acres.

Now, I have tried to tell you about a woman's experiences in ranching. I find ranch life full of joy. To all it is not given to create pictures on canvas or to enrich literature. These are special gifts. But who cannot plant a tree and make a picture against the sky? My memory calls up the picture of the Fresno plains of twenty years ago, covered with yellow stubble, the sun burning down and spirils of dust whirling up like dancing dervishes, the only motion in the tense stillness. Today, my vines and trees spread a living green over these plains, the birds sing, and the cool sweet wind comes over the alfalfa fields where the cows are standing knee deep in the purple tinted greenery.

AMOUNT OF HONEY PRODUCED IN THE UNITED STATES.

At the Philadelphia convention of the National Bee-keepers' Association a few years ago I gave a set of figures going to show the approximate amount of honey annually produced in the United States. This estimate was based on the number of section boxes made and sold by all the manufacturers in the United States, for during that year we learned the entire output. Then the amount of goods sold in various parts of the country would also give something of an idea of the amount of extracted honey produced. Well, this estimate, without going into details as to how the results were arrived at, show that there was 50,000,000 lbs of comb honey and 100,000,000 lbs of extracted, or a total of 150,000,000 lbs all told. The actual valuation of this, conservatively figured, would be about $10,000,000. In answer to a correspondent in our issue for Feb. 15, page 155, I repeated these figures, and the editor of the Pacific Bee Journal compared them with the United States census report of the annual honey crop. He has prepared a new set of figures by putting them in such a shape that they will be more easily understood. According to his way of figuring, my estimate of 150,000,000 lbs of honey would make 7000 carloads. The United States census report on the same basis would make 6667 carloads, or only 333 less than my estimate. These figures are significant when we come to consider the fact that they were arrived at through totally different and independent sources—significant because they are so close together. But my estimate, as made three years ago, was figured on a very conservative basis; and the United States census report of 1899 probably did not take account of all the honey produced. In that, as our readers know, I have questioned the accuracy of the report. But either way we figure it, both estimates are under the actual output of honey in the United States at the present time. I think we should be safe in concluding that we may estimate that the actual product of this country is not far from 10,000 carloads. This seems like an enormous amount of honey; but if one will go through some of the large supply manufactories of this country, and look over their order books, he will have no occasion to doubt these figures—E. R. Root.

Long Lived Tools



Sectional View of Handle Showing Grellner Wedge.

Keen Kutter quality tells in the long life of Keen Kutter Tools as well as in better work and greater satisfaction. It is not an unusual thing for Keen Kutter Tools to be passed down from father to son, so long do they last.

The long life of Keen Kutter Tools compared with the short term of service of inferior brands makes Keen Kutter Tools by far the least expensive tools that you can buy. The

KEEN KUTTER

trademark covers every kind of tools so that you may always be sure of highest quality by insisting upon Keen Kutter Tools.

An example of the Keen Kutter excellence is found in Keen Kutter Hatchets and Handled Axes. These are made of the highest grade of steel, on the most approved lines, and by the best workmen. Every Keen Kutter Hatchet and Axe has the handle wedged with the Grellner Patent Everlasting Wedge which positively prevents the head ever flying off or working loose, and is sharpened ready for use. These are exclusive Keen Kutter features.

E.C. SIMMONS KEEN KUTTER TRADE ST. LOUIS MARK MO.

Some of the other kinds of Keen Kutter Tools are: Axes, Adzes, Hammers, Hatchets, Chisels, Screw Drivers, Auger Bits, Files, Planes, Draw Knives, Saws, Tool Cabinets, Scythes, Hay Knives, Grass Hooks, Brush Hooks, Corn Knives, Eye Hoes, Trowels, Pruning Shears, Tinners' Snips, Scissors, Shears, Hair Clippers, Horse Shears, Razors, etc., and Knives of all kinds.

If your dealer does not keep Keen Kutter Tools, write us and learn where to get them. Send for Tool Booklet.

Every Keen Kutter Tool is sold under this Mark and Motto:

"*The Recollection of Quality Remains Long After the Price is Forgotten.*"

Trade Mark Registered.

SHIPPING FRUIT IN VACUUM.

Editor California Cultivator: Having seen a cutting in an English paper to the effect that a new process of shipping fruit in vacuum, such as berries, cherries and such highly perishable fruit, has been tested with perefct success in California and that the process will come into extensive use in 1906 in shipping fruit to the English markets, I should feel very much obliged if you will kindly give me any information on the subject that you can, and inform me if there is any truth in the report. Thanking you in anticipation.—L. S. W., Lindsay.

Experiments in packing fruit have been carried on by experts for several years past, and various methods have been tried and most of them abandoned, but among many other experiments was one in which fruit was packed in air-tight packages, the air being entirely exhausted and replaced by nitrogen gas. Fruits packed by this method have kept for months and the tenderest fruits have shown no signs of decay after having been packed for long periods.

Theoretically the plan has worked excellently, and on a small scale has given good satisfaction and been apparently successful. The result of these experiments was the organization of a company to do the work on a wholesale plan. This company is known as the "American Fruit Company," and comprises some of the leading fruit growers of California. It has erected a packing plant at Antioch and has been experimenting in packing fruit in large quantities this season. In handling matters of this kind, there is a world of difference between the work when carried on in the laboratory and in the factory, and a great many difficulties have been met with and many of them overcome during the past season, but so far the process has not been sufficiently perfected to make it a pronounced success commercially. The company having the matter in hand, however, is still working and overcoming one difficulty after another and there is little question as to its ultimate success.

The difficulty so far with the process has been in manufacturing absolutely pure nitrogen gas, as a small percent. of the air left in the packages or mixed with the gas or any impurities combined therewith, will militate against it and the fruit packed in impure nitrogen is subject to decay. If the process proves successful, as it probably will, as the parties having the matter in hand will not give it up when they are on the verge of success, it will mean everything to the fruit growers of California and to all other shippers of perishable fruits, as fruit so packed can be kept for an indefinite period and shipped to the ends of the earth. Fruit packed in nitrogen gas has been kept for months without showing the least sign of decay and can be stored in any atmosphere and the packages opened as wanted. Deciduous fruits by this means can be placed on the market any day in the year. The process can also be applied to the storage of fresh meats, eggs, butter, and all other perishable products, and by precluding contact with the atmosphere, the germs of decay are removed and the surrounding gas fills the vacuum and prevents contact with the atmosphere with its putrifying germs.

SAY THE LYE PROCESS SPOILS PEACHES.

A New York dispatch under date of October 1st to the Chronicle says: Several carloads of the 1905 pack of California canned peaches have been rejected here recently by jobbers on the score that the fruit was not up to the contract standard. The imperfect condition of the fruit is attributed to the "lye process" used in peeling peaches.

This process, it is stated, is used by several packers on the coast and consists of spraying a solution of lye upon the fruit, which eats away the peel and saves the cost of peeling incidental to hand peeling. After passing through the first stage the fruit is cleaned mechanically, and those who favor the process say it is none the worse for the operation.

The fact, however, that samples drawn from the pack of several packers by jobbers here on recent deliveries show the presence of lye or other "biting acid" is taken as as an indication that the process is imperfect. One jobber, who rejected a carload, said, the fruit he sampled was so strongly impregnated with lye as to cause a sharp biting of the tongue. This, he believed, would not have a very beneficial effect on the stomach of the consumer.

EXPERIMENTS ON SOILS.

Under the direction of the Purdue experiment station of Indiana the most comprehensive and far-reaching crop and soil experiments ever undertaken in the middle west will be started within a week in Scott and Pyke counties, and will not be completed for ten years, the experiments lasting until 1915.

The experiment, which is made possible by the $25,000 appropriation of the last legislature, will be one in the rotation of crops, and for that reason it will take several years to determine the effect of the rotation on each crop raised. The rotation decided on for the experiment is corn, wheat and clover, in the order named. In each county, sixty-six experimental plots will be planted.

These sixty-six plots will be divided into three sections of twenty-two plots each, and on these twenty-two plots will be planted corn, wheat and clover. The first year No. 1 will be planted in corn, No. 2 in wheat and No. 3 in clover. In the corn section there will be twenty-two plots, and on these different brands of fertilizer will be tested. The same thing will be done on the twenty-two wheat plots and on the twenty-two clover plots.

Professor Arthur Goss, director of the experiment station, and the leading authority on crops and soils in the State, will have charge of the experiment, but will send college experts to conduct the tests. They will take with them consignments of the various fertilizers and plant foods, and will visit the experiment plots often.

The experiments will be conducted in Scott and Pyke counties simultaneously. The results obtained are expected to be the most valuable ever gained from crop and soil experiments and the time involved in the experiments and the money to be spent insures the importance of the tests. The soil on which the experiments are to be made is of the yellow clay variety.

POTATOES, CORN AND WHEAT.

If R. M. B., of Redlands, will read carefully the next few issues of the Cultivator he will get the desired information. Some of his questions have been answered in these columns during the past few weeks.

The total number of crates of cantaloupes shipped during the season from the Coachella district was 10,053. Of these, 4148 were standards, 4599 ponies, 321 jumboes and 975 specials. The average price for standards was 99 cents, ponies 53 cents, jumboes $1.43 and specials 30 cents.

CITRUS FRUITS

By C. A. Day. Pasadena

QUARANTINE AGAINST WHITE FLY

Quarantine established by State Horticultural Commission against the white fly of Florida.

Whereas, information has been received by this commission to the effect that the white fly (Aleyrodes citri) is prevalent in the orange sections of Florida, and that oranges, lemons, and citrus stock in that state are injuriously affected by said white fly; and

Whereas, said Aleyrodes citri does not exist, nor has ever existed, upon such citrus fruits or citrus stock of this State; and

Whereas, there is danger to be apprehended from the importation of such citrus fruits and citrus nursery stock into this State; therefore,

It is declared that a horticultural quarantine be, and is hereby, established against all citrus fruits and citrus nursery stock being imported from the State of Florida into the State of California, and all horticultural commissioners and local inspectors are hereby instructed to hold any and all such fruits or citrus nursery stock, subject to the shippers thereof, for exportation out of the state and to take every necessary precaution for the prevention of the introduction of the said white fly (Aleyrodes citri) into their districts. (Signed) Ellwood Cooper, State Commissioner of Horticulture.

Approved by (Signed) George C. Pardee, Governor of the State of California.

* * *

The above official letter has been sent out to all Horticultural commissioners and inspectors of the different Counties of the State and is along the right line. The several counties of the citrus section of the State of California have county ordinances quarantineing against citrus nursery stock from Florida.

* * *

State Laws and County Ordinances For Quarantine Purposes and For the Eradication of Noxious Weeds and Insect Pests.—It will undoubtedly be of interest to our citrus fruit growers to know that the State of California is well protected by law from the danger of importing into the State upon fruit and nursery stock insect pests foreign to this State. Under special acts by the State Legislature, provision is made for the creation of a State Horticultural Commission and County Horticultural commission.

The State Commissioner is made ex-offico a member of all County Boards of Horticulture and whenever present, acting with said County Board. The County Boards annually reporting to the State Commission.

In the matter of State quarantine, Section 4, of an Act to create a State Commission of Horticulture, says: "Said commission may, by and with the approval of the Governor establish, maintain and enforce such quarantine regulations as may be deemed necessary to protect the nursery stock, trees, shrubs, plants, vines, cuttings, grafts, scions, buds, fruit, pits, vegetables or other articles of horticulture, against contagion, infection by injurious disease, insects or pests, by establishing such quarantine at the boundaries of the State or elsewhere in the State, and he may make and enforce, with the approval of the Governor, any and all such rules and regulations as may be deemed necessary.

In the horticultural quarantine law of the State, Section 1, says: Any person, persons or corporation who shall bring, or cause to be brought into this State, any nursery stock, trees, shrubs, plants, vines, cuttings, grafts, scions, buds or fruit pits or fruit or vegetables, shall, within twenty-four hours after the arrival thereof, notify the State horticultural quarantine officer, or the quarantine guardian of the district or county in which such nursery stock or fruit, or vegetables are received, of their arrival, and hold the same without unnecessary moving the same or placing such articles where they may be harmful, for the immediate inspection of such state horticultural quarantine officer or guardian.

A failure to give notice as provided by the act, is made a misdemeanor.

A number of the Counties of the State have county ordinances which specify that a written notice must be given the horticultural commission or their inspectors within twenty-four hours after the arrival of nursery stock, plants, etc., within the county from points without the county, and the violation of this ordinance is made a misdemeanor and punishable with fine or imprisonment or both. Under the State law and county ordinances the railroad and express companies are obliged to give notice of the arrival of all shipments of nursery stock, plants, etc.

The only loop-hole by which nursery stock, plants or fruit could come into the State or Counties without inspection was the United States mail, and a ruling of the Post Office Department gives the postmasters the right to notify the State and County Commiscions of the arrival of plants or nursery stock through the mails. This ruling is now being taken advantage of in many parts of the State in the case of shipments from the State of Florida.

The State quarantine law and many of the County ordinances make it obligatory for all shipments of plants, nursery stock, etc., coming into the State or County to have plainly marked on the shipment, the name and address of the shipper. All things considered, the horticultural interests of the State of California are well protected by its quarantine laws from the importation of insect pests or diseased stock into the State.

It only requires a faithful performance of their duties by the officials, and the cooperation of the fruit growers and nurserymen to prevent future importations into the State or Counties of insect pests or disease.

We sometimes hear the taxpayer protesting against the expense of the State and County Horticultural Commissions, but when we stop to consider the hundreds of thousands of dollars annually expended by the fruit growers of the State in the effort to partially control those insect pests which have been in a former time imported into the State, and when we further consider the vast sums lost to the fruit growers by the depredations of such insect pests, we can but recognize the benefit and saving which comes from the measures taken to prevent further importation of pests foreign to the State.

Some of our nurserymen have protested against our stringent quarantine laws and the necessary inspection of stock, but if they will stop to consider that this is for the protection of their patrons, the fruit growers, they can but see that they will in the end be benefited by the financial gains that will come to the fruit growers.

* * *

Eradication of Insect Pests and Certain Noxious Weeds Within the State.—The State law governing this gives almost unlimited powers to the officials of the County commissions, but it seems the only way to protect the orchardist from the non-resident owner, and careless fruit growers who otherwise would maintain a nuisance in the way of infected orchards that make a breeding ground for the re infection of adjoining orchards that have been disinfected by their owners.

The State law provides, where due notice has been given, that any owner who shall refuse or neglect to abate the nuisance within the time specified, it shall be the duty of the County Horticultural Commissioners to cause said nuisance be at once abated by eradicating or destroying the disease, insects or pests, or their eggs or larvae, or Russian thistle or salt wort, or other noxious weeds. The expense thereof shall be a county charge and the Board of Supervisors shall allow and pay the same out of the general fund of the county. Any and all sum or sums to be paid shall be and become a lien on the property and premises from which such nuisance has been removed, and may be recovered by an action against such property and premises. A notice of such lien shall be filed and recorded in the office of the county recorder of the county, within thirty days after the right to the said lien has accrued and an action to foreclose such lien shall be commenced within ninety days after filing and recording of said notice of lien and when the property is sold enough of the proceeds shall be paid into the county treasury of such county to satisfy the lien and costs.

Cases under this law have been carried to the Supreme Court of the State and the law has been pronounced constitutional. These measures may seem to work a hardship on careless property owners who fail to comply with the law, but knowing the course of the law the property owner at the present time promptly treats the orchard when notice is given.

The State of California has the most stringent quarantine laws of any state in the union and the large fruit interests of the State require that this should be so.

The citrus fruit growers of our State, subject as it is to the depredations of a large number of insect pests are greatly benefited by our State laws and county ordinances, providing for quarantine and protection from insect pests and diseases.

THRIPS ON ORANGES.

W. S. G., Lindsay, is referred to an article in last week's issue, page 378, entitled "Insects on Orange Trees." The appearance of these insects on orange trees is new to our horticulturists and but little is known concerning means for their eradication. We intend keeping in touch with the study of this pest and so soon as an effective check is found we will publish all the facts known.

NOVEMBER FLORAL CALENDAR.

It is a good time to sow sweet peas just now. It brings them into bloom just when they produce the largest and best blooms. It will pay to spade up the ground just as deeply as possible, even to two feet. This gives not only a good depth of soil, but that good drainage which is so necessary to the successful growth of first class sweet peas. Keep them free from weeds and the surface well loosened at all times.

TIMELY PROPAGATION.

At this time you should take cuttings of soft wood and tender herbaceous plants such as: Allernanthera, begonia, coleus, fuchsia, heliotrope, marguerite, etc. Bottom heat is not needed though better results can be obtained with such a convenience.

Get a box of clean sharp sand, see that the drainage is perfect—plenty of holes in the hottom, wet the sand down thoroughly, put your cuttings in a slit made with a knife or thin paddle, press sand around cuttings and wet down. Watch them closely and don't allow them to dry.

A BAMBOO FOR HEDGES.

We have such a variety of plants used for hedges that scarcely any uew introduction in this line causes surprises to Californians. Yet we must admit that a bamboo for the purpose is somewhat novel.

Of late years the demand for bamboos to be used for hedges and screens, mostly between city lots, is constantly increasing, as no better plant can be found for such purpose. The only drawback is that the varieties geuerally employed, Chinese and Japanese Phyllostachys, have a tendency to send out runners in every direction, which, in many cases, soon become a positive nuisance. There are also two species of arundinaria, from the Himalayas, (A. Falcata aud A. Falconeri), which always grow compact and in clumps, but, on account of not being easily propagated, they have always remained scarce aud too high priced for general use. We have been fortunate to obtain from Darjeeling, 7000 feet altitude in the Himalayas, a new species, Arundinaria Hookeriana, which is much superior to the above named because it grows much more rapidly aud has richer foliage which keeps better in winter. Those who have tried it claim many points of superiority for this plant for use as a hedge.

JAPANESE PINKS.

From the many beautiful flowers that seedsmeu name in their catalogues, it may seem difficult to select the most desirable. But considering the cost of seed, ease of culture, variety and beauty of bloom, together with the lentgh of the blooming season, I thiuk no one will deny that the Chinese, or Japanese, pink (Dianthus) must have a place.

Five cents' worth of mixed seed will yield a surprising variety of both single and double flowers, ranging in color from pure white to the darkest crimson. Put them in the vegetable garden along with the beets and carrots. You might mix a very few early radish seed wtih the pink seed. These will be fit to use before they do any harm to the pinks. Then, if your garden is well teuded, you will be delighted with blossoms nearly the whole year. If they are in the way of the plow they will be all the better transplanted, shake them apart and set one in a place about three inches apart. While they sometimes are all right a second year, it is best to put in a few fresh seeds each year.

DECORATIVE ASPARAGUS.

Two varieties of asparagus are very ornameutal and most graceful in their manner of growth. Asparagus plumosus has leaves as delicate as the finest maidenhair fern. A large plant can be trained to grow on the side of a window or on small trellis in the house. It must have plenty of pot room and the richest kind of soil, as it is a gross feeder. Asparagus Sprengeri is a variety of more substance, having heavier foliage of a deeper green and needs still more food and water. It is a more satisfactory plant than plumosus, standing better indoors. For a pedestal, a bracket or a small round table, it is an ideal plant, as its long sprays will droop all around, forming an object of great beauty.

LOS ANGELES FLOWER SHOW.

The premium list and program of the November Flower Show at Los Angeles has just been issued. Over a dozen cups are offered for various exhibits, for which entries have come from many outside poiuts. The list of 100 patronesses includes the names of the most prominent members of local society. The exclusive right to refreshment booths has been granted free to the Civic Federation of Women's Clubs, the members of which are greatly interested in the work, for the entire proceeds of this feature of the show are to go to their school garden fund. An orchestra will be present each evening, beside a special musical feature. On Saturday evening the refreshment dispensers will all be dressed in Spanish costume and serve Spauish drinks, and dishes, an exclusive Spanish orchestra will be on hand, and everything will be done to make the eveniug seem to visitors like one passed in the heart of old Mexico.

The exhibition of flowers and plants will be the finest ever seen in Southern California. So many eutries have been sent in that the Association was forced to procure Symphony hall, which connects with the main exhibition hall (Blanchard's); and have had to refuse several proferred exhibits. Membership for the current year (1905 only) costs three dollars, but every member will receive a season ticket for self and lady, which if used every evening, will give him his entire investment back. Don't forget the dates. November 2nd, 3rd and 4th. Further information furnished by the Secretary, Ernest Braunton, 203 New High Street, Los Angeles.

LIQUID MANURE.

The best all round liquid fertilizer can be made from cow manure. Make the liquid in a barrel or tank, and when drawing it off dilute to about the color of weak coffee aud apply once every five or six days, according to the needs of the plants. This will do both for roses and carnations. If the cow manure is not obtainable, sheep manure will suffice, or ordinary stable manure. If sheep manure is used, care must be taken against using it too strong or more harm than good will result. In feeding with liquid, it is well to know that a weak solution applied often is better than stronger ones given at longer intervals.

WATERING PLANTS.

When you water plants, soak them and have done with it. It is the little dabs of water all the time that do mischief. Out of doors it doesn't rain every few minutes but when it does it soaks and then stops. Morning is the best time to water. If you have house plants, stand the pots in a tub of water, deep enough to reach almost the rim of the pot. When the soil turns dark on the top take them out and drain before carrying in the house.

HOUSE FERNS.

Only a few of the many varieties of ferns will do well under ordinary house conditions. Most varieties are too sensitive to the extremes of temperature and the dry air commonly found in living rooms. The Boston fern is probably the hardiest of all and most easily grown in the house. It requires a rather light soil, to which has been added some leaf mould, and the roots must be kept moist but not too wet or be allowed to dry out. Spraying once a week is useful to keep the fronds free of dust, as well as to prevent the attacks of scale and insects.

BISULPHIDE FOR ANTS.

Where ants infest lawns, punch holes about a foot deep with a stick at three or four points near the center of the nest; pour into each about an ounce of the bisulphide of carbon and close the openings with the foot. The vapor will get into and follow the galleries aud kill the ants. A second treatment will rarely be necessary.

DAHLIAS.

It is rather the fad in these days to cultivate old-fashioned flowers of all kinds, aud among the old-time favorites none has come back into fashion with greater emphasis than the dahlia, largely because of the many late improved types. The attention which is being bestowed upon this flower is well deserved. It is really a species of more than ordinary merit. While the old-fashioned varieties are worth preserving, there are some improved strains which are far ahead of them. The modern cactus dahlia is particularly interesting, graceful and attractive, aud is each year growing in popular favor. Every season sees new and more beautiful types until now the Dahlia is forcing attention even among the growers of cut flowers for the market.

DRAINAGE THE SURE CURE FOR ALKALI LANDS.

The only really effective method of reclaiming alkali lands is to remove the soluble salts from the soil. This may be done in many cases, where the soil is of comparatively coarse texture or the location is favorahle, by making open, deep ditches at different intervals in the field and soaking the soil thoroughly. Quite a number of Utah farms have been reclaimed from the alkali scourge in this way. The better way and in most cases the hest manner of reclamation, is to lay a system of tile drains which, under the influence of heavy irrigation will carry off the soluhle alkali of the soil. It is urged against this method that it is very expensive, and that the farmers of this state cannot afford it.

Considering, however, the value of an acre of irrigated land, and that the great majority of lands trouhled with alkali would he among the most valuable lands in the state were they reclaimed, it would seem to be a wise investment financially, could they be reclaimed at a moderate cost. The expense of underdraining does not need to be excessively high. There is plenty of clay in the state and should the demand for tile drains arise capital would gladly establish tile factories wherever necessary.

In fact, the average alkali lands of the state could be drained at an expense of from $10 to $17 per acre, with an average cost of perhaps $13 or $14 per acre.

There is, of course, considerahle hesitation on the part of farmers to undertake draining, since they are not certain from their own trials or from those of their neighbors that the method will be successful in removing the excess of alkali.—Desert Farmer.

The trustees of the Fruitvale school district in Riverside Co., have a plan made for a garden. They have written the County Superintendent of schools for seeds, and propose to raise and sell sufficient vegetables to buy pictures for the school walls, a croquet set, etc.

In the Vegetable Garden

WHERE ONIONS GROW.

Down near Westminster, in Los Angeles county, they are growing onion sets by the ton. Mr. S. J. Murdock, one of the heaviest growers in that section, states that the acreage this season is from 18 to 20, which will produce 40 to 50 tons. Last year the output was over 60 tons, but the late rains which prevailed on the mountains did not reach this district, hence the light yield. Had the main crop been planted earlier, all would have been well.

The demand for these sets far exceeds the supply and orders for at least 40 tons in excess of the crop have been received. The soil in this district is a heavy, black slough land, well supplied with humus and fibrous content from the tules, grasses, etc., and from the same source, through years of burning off comes a good supply of potash. In some parts a heavy per cent of alkali is present, but nowhere in sufficient quantities to prevent a crop of onions. It is claimed for the onion that it will thrive where so much alkali is present that celery will not grow.

Their main seed planting season is from February to April, though some is done as late as July 1st. The rows are placed but eight inches apart and as is the case with all set growing, the cultivation is all hard work. The crop is never irrigated so that damp lowlands are most desirable. When first settled the water almost stood on the surface, but by under-drainage it is now four feet below.

The sorts mostly grown are the Australian Brown, Strasbourg, Philadelphia Silver Skin, Extra Early Pearl or Barletta, and the Queen.

GROWING RHUBARB.

A sure way to successfully grow pieplant is as follows: If possible, have your pieplant in the shade of trees; the more shade the better. Cover the bed four to six inches deep with well rotted stable manure, then spade it as deep as you can, mixing the manure with the earth as much as possible. Set your plants three feet apart each way then spread evenly over the entire bed four to five inches of new stable manure. The stalks will grow ranker if a barrel with both ends out is placed over each plant. If you have plenty of shade the barrel is not necessary.

A CALIFORNIA-TEXAS DINNER.

It was our pleasure a few days since to sit at a table in a Texas home, on which a tasteful variety of foods was spread. There was crisp lettuce, delicate cauliflower, firm, red tomatoes and fresh roasting ears making up a delightful vegetable dinner. We remarked on the perfection of these vegetables and were informed that each and every one of them came from California in refrigerator cars. We were curious as to the cost of these imported items and were told that each dish represented an expenditure of only five cents at the grocer's. The table seated six persons.

Further investigation showed that these vegetables were grown under irrigation in far-away California. We pondered the facts. Why should Texas be a summer market for California vegetables? There must be ten thousand Texas families in towns and cities today eating from the same fields on which grew these vegetables. How can a Californian, on $200-land, buy irrigation water, grow a crop in midsummer, pay freight and refrigeration for a 1500-mile shipment and sell his product through retailers to consumers at reasonable prices? Here is certainly skill in growing; but most of all the system of distribution and marketing strikes one with peculiar force. The commercial instinct has been developed in connection with the growing of these California products so that the world's markets are conquered by the very cheapness of the goods offered.—Farm and Ranch.

PREVENTING SCABBY POTATOES.

Scab on potatoes can be very effectually controlled by soaking the seed potatoes in a solution of corrosive sublimate, dissolving two ounces of the powdered article in two gallons of hot water in a wooden or earthenware vessel. When thoroughly dissolved add it to thirteen gallons of water in a clean barrel, allowing it to stand two or three hours with frequent stirrings in order to have the solution uniform. Either before or after cutting up the seed, place it in bags and dip it in the corrosive sublimate solution and allow them to stand in it for an hour and a half, when it should be taken out and other sacks of seed similarly treated, as long as the water holds out. If this seed is sown on land reasonably free from scab the crop will seldom be seriously injured. However, land infested with the germs of potato scab will produce a more or less scabby crop, no matter how clean or smooth the seed used, or how free from fungus it may be.

Scabby potatoes should be dug as soon as matured, for the fungus disease continues to grow and injures the potatoes as long as they are in the ground. Potatoes may be grown from seed very similar to that of growing tomatoes. However, the little plants should be put out the first year as close as six inches apart. At the end of the first season the tubers will be about the size of hen's eggs, and should be stored and cared for in a way similar to that of other seed potatoes. The next season with good care they may be expected to produce tubers of the usual size. It is not usually possible to get seed from our common varieties of potatoes, but most seed houses carry the seed for sale in packages at about five cents each. We commend the growing of potatoes for seed as a very interesting and useful line of experiment, as each seed represents a new variety, so that in a hundred plants scarcely two of them will look alike, varying in color from dark blue to pure white, and differing in form and color of the eyes as much as any of the cultivated varieties. New varieties originated in this way are likely to have renewed vigor, and if possessed of other valuable qualities will make useful additions to the list of cultivated varieties.—Farmer.

TOMATO BLIGHT.

For several years the experiment stations have been trying to solve the tomato blight malady of the arid sections. So far from all the investigations made, no certain bacteria can be ascribed as the cause. Demonstrations at the stations show that in beds planted with tomatoes, and which for a year or two previous had heavy dressings of barn yard compost added to the soil that in such plots there was considerably less blight than in beds not so treated. This fact has been verified at different places and in different years. In other words, soils which analyze a high per cent of potash when diluted with humus and nitrogenous elements produce plants which show a less tendency to blight. It might be interesting to have this experiment carried on a little further in the same direction; it might lead to a more formal conclusion as to whether or not the caustic effect of potash under conditions of high temperature and moisture injures the tomato plant. Excessive potash under certain conditions, like alkali, is injurious to plants, while in moderate amounts under proper conditions it is very essential.

The point made by speakers, at the meeting of the commissioners to locate the new Pathological Laboratory and Experiment Station, that the station should be placed where there is most activity in pest development was well taken, but it appears to a disinterested looker on that about every locality in Southern California has its line of pests and it would be a difficult matter to find a place where these pests in abundance do not appear with unerring certainty.

FOREST LOOT.

The great forests of the Pacific slope contain the finest mercantile timber in the world today, said a prominent Californian who was recently in Washinton. But the noblest of forests are fast being mowed down before the swath of commercialism, regardless of future lumber supplies or the source of our western water supply. Notwithstanding the vigilance of the government agents the work of despoiling timber lands of the coast goes merrily on. The forest lands of the Mississippi valley states are almost bare and the timber grabbers are working in full force in the unrivalled pine and cedar forests of Idaho, Washington and Oregon and in the redwood belts of California, yielding their almost incomprehensible cut of timber per acre. It is commonly believed in the west that unless some drastic action is taken there will be no virgin forests 20 years from now, except in the forest reserves.

Governor Pardee has received the following letter from the President of the American Chamber of Commerce in Naples, Italy:

"I assure you that I will do all in my power to place the resources of the State of California before all interested parties, and anything that you may send to this Chamber of Commerce will be placed in a prominent position without any charge whatever. Therefore should your State Agricultural Bureau desire to place a small exhibit I shall be pleased to see that same is taken care of. Of course such exhibit should be delivered free of all expenses in Naples.

Yours very truly,
J. P. Spanier, President.

Test of the President's Rate Bill.—Under date of October 12, the Washington Post gives what purports to be President Roosevelt's views formulated in sections relative to railroad legislation to come before Congress this winter. Last winter a bill known as the Esch-Townsend measure was passed by the Lower House. It is this bill which the President wishes modified in several important particulars. The Post says the following on the President's announcement:

1. That the interstate commerce commission shall be given the power to decide, upon complaint after full hearing, whether a rate is unjust or unlawful; that the commission shall have authority to substitute a rate which shall become immediately effective and so remain, unless and until reversed by the courts.

2. The commission shall have the authority to declare that a rate charged for shipment on private cars is unjust or unreasonable, if it be so, and that the common carrier shall be held responsible for such charges.

3. Giving the interstate commerce commission jurisdiction over terminal railroads.

4. A reassertion of the long and short haul provision of the original interstate commerce act.

5. A provision relating to the shipment of merchandise by water and rail, so as to prevent manipulation of rates, made possible in such circumstances under the present law.

6. Giving the commision full authority to examine the books and records of the railroads and to prescribe the general form and manner in which such records shall be kept.

It will be observed that each one of these provisions goes straight to the cause of complaint by the shippers. If the rate is shown to be excessive the Interstate commerce commission has the power, under this clause, to modify it, and to make one which will be just. This is the whole matter in the contention of the shippers of California today. They claim that the rate on their products is out of all proportion to their net receipts, and further that the railroads can carry their consignment at a much less rate and still derive a handsome revenue from the business. If the interstate commerce commission is clothed with mandatory authority, and is composed of business men, it can easily learn what a just and unjust rate is by a computation of distances, expense of hauling and operating cars without taking into account at all what the producer receives for his foods.

It is the just rate which is wanted, a rate based upon fairness to the railroads and justice to the shippers. No well-meaning man desires to entail upon the transportation companies ruinous or even burdensome laws. They have their rights, but they have gone beyond those rights and exacted tribute where none was due them and it is because of this that the protests of the producers and the shippers have found lodgment in the ear of the country and the mind of President Roosevelt.

* * *

Assuming Political Character.—The railroad rate discussion appears to be assuming a political character if we may judge from the editorial comments of leading newspapers throughout the country. The President and the Republican press, of course, stand squarely for a rate law, to be operated by the Interstate Commission.

On the other hand certain Senators are opposing any change in the law and among them are members of both the great political parties. The following from the San Francisco Chronicle's editorial page shows the trend of discussion so far as the republican view generally is expressed:

The railroads control the Senate because they control Legislatures which elect the Senators. They control the Legislatures, not usually by direct bribery with money, but with regular yearly incomes paid to their henchmen for attending to some duty. To a small extent only do these incomes come from the railroad treasuries. They would not trust such cattle as they hire for such purposes about their offices. For all business connected with the operation of their systems they will employ only men of approved character. The regular incomes provided for the men whom they hire to do their dirty work the railroads insist on having provided by somebody else, and that "somebody" is invariably the public. If any one desires important office—state, municipal or Federal—he can get railroad help or escape railroad opposition only by delivering his patronage to the railroads for the support of their roustabouts. This is true in every state in the Union. The railroads everywhere endeavor to control Federal, state and municipal offices, and, as leading to that, the party organizations."

This is a very strong arraignment of the railroads to be made at this time, but later developements may bear out its truth.

* * *

Renting vs. Owning Land.—If the Cultivator were to offer advice to young men who contemplate making farming their permanent occupation, it would say, buy land, don't rent. "A renter once, a renter always," is a maxim which has more truth in it than fiction. Horace Greeley, once said to a Colorado farmer, a young man, who sought his advice on this subject, "a renter never amounts to anything, own your own land if it is only an acre."

In line with this advice comes the following from the Earth, an agricultural journal in Illinois:

"Young man, don't rent land if you can possibly help it. Buy some kind of a farm if you haven't a cent to pay down on it. Make up your mind to hold it, and do it at all hazards. The renter is never given the slightest show on earth. The landlord usually wants cash rent. He will rent the farm to you only from year to year, as he might get an advantageous opportunity to sell it. You feel no interest in the place, and this naturally causes you to fall into slipshod, shiftless ways. Then again, the place you buy when you are young will be worth when you get old just twice as much as you paid for it. Quit renting and buy you a farm somewhere and never let it go.

* * *

Farmers' Institutes.—The season for the opening of Farmers' Institutes in Southern California is near at hand. Prof. E. J. Wickson, dean of the Agricultural College of the University of California, was in Los Angeles last week, and from him the Cultivator learns that very soon now, a manager will be appointed for Southern California who will arrange for twenty-five institutes. Dean Wickson informs us that the agricultural faculty of the University will be called into service to attend these institutes and he expects to make them better, in all respects, than they have heretofore been. The Cultivator would advise localities ambitious for institutes to make application to Prof. Wickson, Berkeley, at an early date.

* * *

Will Congress Never Act?—The need for immediate and radical action by the Government to check the inflow of undesirable immigrants is increasing today with a greater force than ever before in the history of the nation.

Last month over ninety thousand immigrants arrived in New York, and this is an increase of eight thousand over the corresponding month of last year. The greater part of these people came from Eastern Europe and only about 20 per cent. of the total can be classified as desirable. It is evident that the influx is not to be stopped by discussion, of which there has been plenty, and the immigration authorities cannot wake up from their present trance too quickly.

* * *

A Blot on Our Civilization.—If the telegraph dispatches from Chinese ports are to be belived, a most infamous traffic is being conducted in American girls for Chinese slaves. Both at San Francisco and Chicago, men and women are engaged in this abominable business and innocent girls are being exported under contract as governesses in wealthy families, when in fact they are to be used for immoral purposes. Some of the girls, when their fate became known, committed suicide. It seems there is no Federal law to reach this business, but there should be, and Congress ought to make one this winter which will be so drastic as to forever put a stop to the nefarious traffic. Let American girls, all over the country, beware of inducements held out to them by advertising firms to accept places in families in foreign countries as governesses, or maids to high dignitaries, women we mean, for at the bottom of the propositions, they may rest assured is a slavery worse than death.

* * *

Short Course in Agriculture.—The State University has provided a short course in agriculture for those desiring such instruction. It will embrace such studies as are pertinent to California farming in general. Prof. Wickson, dean of the Agricultural College will furnish all needed information on application.

* * *

THAT BAREFOOT TRAIL.

Over in Iowa there is a man constituted along the lines of the "good old days," before so much moral philosophy was applied to the boys and girls of that periad. This man whose name is Edward Sabin has just published a little peom entitled "The Barefoot Trail," in which so much simple rural life is crowded, as to be extremely refreshing. The Des Moines Capital, whose editor knows Sabin, as we know him, simple hearted and free from all form of vain glory, says of the poem: "When Mr. Sabin wrote those verses he was not worrying about any of the perplexities as to whether heredity or environment play the greater part in the development of a child. He simply threw some of his own youthful recollections and observations in and about Clinton, in this state, into uncommonly fetching jingle and rhyme. "The Barefoot Trail" was such as all village and country boys followed in that day over the hills, across the meadows, down by the river, through the woods, and when the day was done "back to home and mother again."

We all have in memory some barefoot trail, which we followed as boys and girls, on which we sniffed the ozone from the redolent air, while our feet tingled with the cool dews of the early summer morning. The barefoot trail worked all right then. It would work all right today if we could give it the same opportunity it had fifty years ago.

The tendency nowadays is to fuss over children too much and watch them too incessantly. The let-alone doctrine ought to have a time and place. Boys and girls can attend to a part of their development a good deal better than anyone else can do it for them. Let nature have her own course for a part of the time at least. If this thing keeps up of mothers attending scientific discussions of environment versus heredity and then going home to superintend every move the youngsters make from Monday morning to Saturday night is not stopped the life of childhood will hardly be worth living any more.

Some one has said every man has two educations—one that is given him by others and the more important one he gives himself. The modern isms on child culture ought to have a rest. Youngsters will get some mighty good schooling while following "The Barefoot Trail," and the other part will follow naturally enough later in the day when they get "back" to home and mother again."

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

Banning reports state that the prune and almond crops in that vicinity have been unusually good, with prices at top notch.

The pear and apple crop around Downey is but little over half a crop, the cause supposedly being the late, backward spring.

O. S. Jordan of Whittier, receives $2700 for the Valencias on 290 trees net, or more than $9 per tree. How's that for profit?

Reports of the grape crop around St. Helena show that the crop was even lighter than expected, but experts state the quality of wine made has never been surpassed in that district.

The California Citrus Union received this week $1051 for less than a carload of Valencias which the Union packed for Porter Brimmer, of Rialto. This included standards, and netted for the grower more than 4 cents a pound.

The cantaloupe acreage for 1905 in the Coachella Valley was 690 acres. This crop together with their watermelons and grapes has brought them a rain of double eagles, for all of the past season's crops came fully up to all expectations.

Advices from Vancouver, Washington, are to the effect that the prune crop has turned out a great deal better than at first expected. It is probable that at least 150 cars will be packed in that district. The prunes are all very large, a great many grading from 20 to 30 to the pound.

One of the Cultivator staff, writing from Lompoc, states that the valley has had a prosperous season in all lines; apples fine, with heavy crop; grain yield good; mustard (an important local industry) has yielded well; hay crop, fair, but extra quality; stock, poultry, etc., in thriving condition; he says: "I tell you Lompoc is on the map all right."

The Golden State Fruit Company of Ontario, under the management of L. E. McCann, has had a prosperous season. The capacity of this plant is 40,000 cans per day of ten hours. The total pack for this season is 1,100,000 cans, 2,200,000 pounds of fruit having been used to fill this number. With the exception of 185 tons all was raised in and around Ontario.

La Harbra Vegetable Growers' Association sold by contract to the California Vegetable Union Monday of last week their entire crop of tomatoes. It is estimated that the crop will amount to about 900 tons first grade and 600 tons second grade, or a total of 1500 tons. About 300 acres are in tomatoes and the starting price will be $30 a ton for first grade, or a this price the crop will bring $27,000 for first grades alone.

The date trees at Hanlon's near Yuma are being picked of their annual crop, which is said to be unusually large. The Indians are carrying them away by the burro load, as no attempt is being made to market them. While of an unnamed variety, the fruit is of excellent quality, and were an attempt made to sell it, there is little doubt that it would bring a good figure. For many years the trees have borne splendid crops, affording ample evidence of the future for the date industry in this section of the United States.

For big net profits in oranges, the Coulter ten-acre place, two miles east of Fullerton, is a record-breaker. Three years ago the orange crop from this place, which is not all set to oranges, sold for $6250; two years ago it brought $5150; one year ago the income was $4900, and this year the oranges sold for $8658 net.

A North Yakima, Washington, report says that from the present outlook the quality of the apple crop will be unusually good, though the crop is somewhat short. Winter pears are also being heard from and in both cases prices are good and will probably remain so.

AGRICULTURE.

Sid Gray of Downey, planted alfalfa in February and has cut five crops, the last one over a ton to the acre and the sixth is nearly ready for the mower.

Ranchers in the Imperial Valley have appealed to the Secretary of the Interior at Washington to take measures to stop the overflow of water into their region.

The beet dump at Somis closed a successful season on Saturday night. In the neighborhood of 20,000 tons will have been harvested between July 31st and October 21st.

The first celery has been shipped from the Smeltzer district, to Chicago. There is a greater demand for this succulent vegetable than ever before. The local crop is heavy and in prime condition.

The sale of public lands in California since the reclamation act became a law, amounts to $2,333,466.08, all of which figures go into the general reclamation fund which now amounts to about $30,000,000.

Robert Gauss of Denver, after experiments of 15 years, has developed varieties of wheat, oats, barley, and rye which give remarkable yields without irrigation other than that of the slight rainfall on the plains.

Farmers in the northern portion of Yolo County are circulating a petition which will be presented to the Board of Supervisors, asking that they pass an ordinance making it compulsory on the part of farmers to put out poison for squirrels.

The bean thrashing is neary ended and if good weather, it will be finished in a week. This week there were six large outfits in sight of Oxnard. The machines are running from daylight until 9 and 10 o'clock in the evening. It now looks as if the output of beans for this season will exceed 625,000 sacks.

The bean raisers of District 70, near Yuba City, have finished harvesting their crops, and now have nothing to fear. Had there been a little rain several weeks ago the farmers would have suffered a heavy loss. The weather has been ideal. and the beans averaged about forty sacks to the acre, which is good.

The shortness of the wheat crop in Mexico is greater than was estimated a few weeks ago, and millers are looking for the entire removal of the duty on American and Canadian wheat by the first of next year. The city bakers have reduced the size of their loaves, asserting that it is impossible to give the same weight as formerly.

Monterey county reports the best barley crop in twenty years, upwards of 100,000 tons. Wheat and oats were light on account of rust. The potato yield was immense, over 60,000 tons of most excellent quality will be harvested. 20,000 tons of beans have been marketed as well as 200,000 tons of beets, with more to follow. This has been a splendid year for Monterey county.

The gathering of the pear and peach crop around Hemet is drawing to a close. Harvesting of the olive crop will soon begin, and next month digging winter potatoes will be started. In the latter part of November and early in December Hemet should make carload shipments of navel oranges for the Eastern market. In this valley seed time and harvest time are perennial.—Hemet News.

Horst Bros, of San Francisco have, by a succession of deals, obtained control of the whole hop crop of the lower mainland of British Columbia. They have for some years been growing hop at Chilliwack and Agassiz, having 130 acres owned or leased in the former district. Lately they have bought the crop of H. Hulbert, who has forty acres in Chilliwack, adjoining the Horst farm, and by a number of deals have secured 150 acres from surrounding farmers.

Wheat and barley crops in the San Jacinto grain district were unusually large, hundreds of thousands of sacks of grain being threshed in the last few weeks. In the Yucaipe Valley there has been one of the best seasons known in several years, considerably over 100,000 sacks, while in the Moreno, Perris and Alessandro Valleys the output has greatly exceeded these figures. The total estimate runs into almost half a million sacks. Some of the barley has run 120 pounds to the sack.

The Kern County Echo says: "H. G. Kincaid who was in town from the Weed Patch yesterday, says that he is harvesting fifty-two tons of Egyptian corn from thirty-five acres of land. The greater part of the crop was from twenty-five acres of land, and Mr. Kinkaid credits the great yield to the manner in which he cared for the corn. The twenty-five acres where the best corn grew was irrigated before the seed was planted. When the corn was about three feet high it was irrigated again and then cultivated. When the heads were forming the corn was irrigated for the third time. The usual way is to irrigate only before planting, but Mr. Kinkaid says that the extra crop he is getting more than pays for the extra water and labor."

LIVE STOCK.

The wool growers about Petaluma have about all decided to hold on to their fall wool, as there is practically no market for that commodity at present.

Practically all the wool in the warehouse at Ukiah has been sold, the first lots going Wednesday night and Thursday morning. The prices were from sixteen to nineteen cents, the average being about 17 1-2 cents. About 600 bales changed hands.

The American Stock Growers' Association and the National Live Stock Association will make a joint fight against the national convention at Chicago being "packed" by the railroads. The stock men want better rates and several changes in the existing rules.

MISCELLANEOUS.

At Las Vegas the Salt Lake Railway Company is building a depot which will be the handsomest structure in the whole desert region. It is modeled on the mission style, something like the depot at Riverside, and luxuriously appointed for passengers.

Ten carloads of horses, scrapers, dump wagons and other railroad building material arrived in Marysville yesterday and will be used by the Pacific Coast Construction Company to build the Western Pacific Railroad from Marysville to Oroville and south from there to Stockton.

The Redding Land Offices received notification from Washington making permanent the Mount Shasta forest reserve, comprising about twelve townships in Shasta, Trinity and Siskiyou Counties and taking in Mount Shasta. Thousands of acres of land along the Sacramento, Pitt, Scott, Klamath and Salmon Rivers are withdrawn from entry and settlement.

C. H. SESSIONS, ASSOCIATE EDITOR

MONEY IN MULES.

Since the Boer war, mules have been worth more for draft purposes than horses. The country has been literally drained of this valuable farm auxiliary, so that today a span of good mules costs from $300 to $400. In California the demand for mules exceed that for horses.

The point about the mule is that he is better liked, as a general thing, by farmers, than the horse. If he is treated decently and fairly fed and groomed as the horse is, he is the kindest, best behaved domestic animal on the farm.

It is a fact, and all users of the mule will tell you so, that his virtues are less understood than any animal we use. He is "cussed" more and oftener, beaten with clubs, and struck with stones when he does not deserve any such treatment. We remember, while in the service, hearing General Thomas reprimand a mule driver for beating his mule team. He said, "Young man, if you will stop pounding your team and talk good horse sense to it you will get your wagon out of that rut," and taking the lines from the driver's hands he quietly patted the leaders, one by one, spoke kindly to each, and after a moment or two of silence said, in a mild but firm voice, "go on now," when lo, the team started and pulled the load out of the mire. Handing back the reins to the driver the General said, "You see, young man, it pays to treat even a mule with kindness."

We remember reading, not long since, the following about the mule and his virtues:

"Often in farm papers letters appear from men who are familiar with mules both in raising them and in doing all sorts of work with them, and it must be admitted that whatever is published about the animal from any point of view is in its favor. This being true, why is it that there is such a strong prejudice against mules?

I have owned a good many farm mules, and inasmuch as I grew up on a southern plantation, where I was perfectly familiar with them and often rode them and drove them from preference, I think I can pronounce a strictly unbiased judgment upon them. I therefore say with certainty that most of the bad qualities attributed to the mule are slanders.

They are not kickers or balkers, are not stubborn and are not tricky. These are the most common slanders. They are faithful workers, can live on less than horses, last longer, are more healthy, less likely to run away, and can stand hard usage far better. With these points in their favor, they are more desirable for most places than horse colts, and there is more profit in raising them. If a man is raising horses to sell, I think, unless he is very far north, where the demand for mules is light, he would do better to raise mules instead. If one has large sized mares, say 1300 to 1500 pounds, and will breed to a large Spanish jack, the chances are that he will have young mules that will bring fancy prices. I have never known a time when good sized, smooth, stocky mules did not do this.

The average selling price in all markets is and has been higher than that of horses, and unless one happens to be outside of a region where mules are in demand, they can at any time be sold at satisfactory prices. This fact is being recognized by horse raisers in some of the States, and some of them are going into mule raising as a better investment.

Therefore, if I were going into stock raising, I think I should try mules as being the safest and most profitable."

DAIRY EXHIBIT AT THE KANSAS STATE FAIR.

The chief feature, and probably the most interesting exhibit at the Kansas State Fair, at Topeka, Kan., says the Kansas Farmer, was the dairy exhibit of the Kansas State Agricultural College. It consisted of a complete working dairy, with the various kinds of butter making apparatus, such as cream separators, pasteurizers, coolers, churns, workers, and a complete labratory for testing the milk from the cows that entered into competition.

A very attractive part of the display was a miniature model of the Kansas State Agricultural College dairy building, which was made of butter and in connection with this was shown all the various products made from skim milk, such as dried casein, glue, sizings, water paints, milk sugar, etc. The amount of starch, protein, and fat contained in 100 pounds of alfalfa hay, prairie hay, clover hay, corn, linseed meal, and bran was also shown.

The exhibit excelled in extensiveness any display that has ever been erected at any State fair west of the Mississippi river. The management of the fair considered it one of the most attractive exhibits ever displayed on their fair grounds.

The Agricultural College deserves much credit in taking advantage of the opportunity, and making the best exhibit they could under the circumstances. The dairy at the college is well equipped and has been doing much good for the dairy business of the agricultural industry of Kansas.

SORE NECKS ON HORSES.

The most of the machinery now used on the farm is balanced by the tongue, and consequently a great deal of weight comes on the horse's neck, which is liable to get sore during the hot weather. I know how disagreeable it is to drive a horse with a sore neck, besides the pain and annoyance it gives the horse, writes Forest Henry in Northwestern Agriculturist. I find that the trouble can usually be avoided by observing the following rules: Never check the horse while at work so he cannot lower his head and work the collar front slightly while standing. You will always notice that it is the horse that carries his head high that is most liable to get a sore neck. See that the collar fits the neck of the horse so that it will not work from side to side as he walks. See also that it is not too short. A short collar is sure to make a sore neck in warm weather.

See that the hames fit the collar. A hame that has to be let out by lengthening the strap at the top is also liable to make a sore neck. As the horse pulls the hames will spread on such a fit, pulling the collar together endwise and spreading it at the same time so it will work back and forth and is sure to cause trouble. For this reason I prefer the high hame to the short one. With the short hame any alteration has to be made by lengthening or shortening the strap, while it is the hame that should be shortened or lengthened. I have found a sole-leather pad that is very generally used a very good pad for the top of the collar. A pad made of deerskin and heavy harness leather is excellent, where the collar is long enough to admit of its use. It requires a collar an inch longer where it is used than with the leather pad.

A sore neck is usually preceded by

a bunch coming on the top of the neck where the collar rests. If this is left and the horse worked it soon becomes a deep seated sore, causing no end of trouble. If this bunch is noticed the first day it appears it can be entirely removed and the horse worked continually if the cause of the trouble is removed and the hump treated with oil of spike every night and morning. It pays to look after the welfare of the horse, as he is our main dependence during the rushing work of summer, and a horse with a sore neck cannot do his work easily nor as satisfactorily as though he were sound. It never pays to overdo a horse when the weather is excessively warm, as he is almost sure to get sore shoulders or a sore neck, no matter how well his collar fits, if his blood gets overheated. It will often pay to give a horse a pail of water between meals in very warm weather. It may mean some work; but it will pay in the long run to not neglect anything that will add to the comfort of the hard-worked animal.

FEEDING FARM HORSES.

Information regarding the feeding and management of horses is presented, some of the data being based on the experience of the Utah Station. The principal points are thus summarized:

"The amount of hay fed to horses on the average farm can be very materially reduced, and if this be done it will result in (a) great financial saving to the State, and (b) the elimination of many digestive disorders to which our horses are subject.

"Horses should receive most of the hay at night, very little in the morning and none at all for the noon meal. Always water before feeding. Oats make the best grain feed for horses, but these can be replaced by bran and shorts, or supplemented by corn.

"Carrots and sugar-beet pulp have a marked beneficial effect in horse-feeding, serving as a laxative and a tonic, as well as enabling the horse to digest the hay and grain more effectively. Horses may eat as much as 40 pounds of sugar-beet pulp daily."—L. A. Merrill, Utah Farmers' Inst.

THE CITY MAN AND THE CALF.

We bought a little place of forty acres, a convenient little house and a small barn. Our family at the outset consisted of myself, my wife, my daughter Nellie, aged 18; my son Robert, aged 15; one horse, Billy, of uncertain age, and two cows, Molly and Betty, the number of whose years I never cared to inquire.

As I said before, I had no doubt of my ability to run the farm. As a matter of fact, though, for the first year that farm ran me. It ran me into debt, too, but the next year it ran me out of it, and now I can afford to look back and laugh at my experiences, for I can see myself as my neighbors saw me at that time.

I had figured out an extravagant profit to be made from those two cows. In my calculation, however, I had assumed that they would give milk all the year round. Consequently, my estimates were somewhat broken up when Molly went dry, and a little later presented an addition to our family.

That calf was indeed a problem. I left him with his mother for two weeks, but I begrudged him every swallow of milk that went down his greedy throat. But I didn't know what to do with him. I decided at the end of two weeks, however, that the troublesome youngster was old enough to take his meals from a pail, and I set a tempting display of lacteal fluid in which was a liberal supply of bran, before him. He looked at it, sniffed, looked at me and backed away. I caught him by his two long ears and pulled him up to the pail again. As soon as I released him he began another retreat. I reached for him again, but he made a sudden shift sideways, and I came down on my hands and knees with one arm up to the elbow in the pail of milk.

Then I arose in my wrath and seized that calf. I placed my hand on his head and pushed his nose into the milk up to the eyes. But he wouldn't drink. When I feared he was about to smother I released his head, which came up dripping and white, the thick cream forming a fascinating semi-circle just under the reproachful eyes, which he lifted up to mine, while he gave vent to a long and vigorous verbal remonstrance.

At this critical juncture there appeared upon the scene my son Robert, and that young hopeful had in his hand a piece of old garden hose about ten feet long. "I'll tell you how to make that calf drink this," he said "Just make a siphon with the hose and put one end in the animal's mouth and the other end in the milk pail."

"My boy," I said, "you are certainly a chip off the old block, for you are a genius."

We put the pail of milk on the stairs leading up to the hay loft and Bobbie held the hose while I caught his calf-ship.

I got behind and shoved the refractory beast to the foot of the stairs, and after considerable labor inserted the hose.

The milky stream began to flow. The calf began to gasp and his eyes rolled until they looked like two glass agates. He tried to bolt, but I held him fast.

The milk trickled out the corners of his mouth and ran down to the floor. But the obstinate animal wouldn't swallow. He chocked and gasped, but wouldn't let a drop go down his throat. I just determined to push the hose down into his stomach when something happened. The calf closed his teeth on that hose and suddenly lay down. Robert was not prepared for that move. The pail of milk came over in answer to the pull on the hose, and I found myself a moment later emerging from a most unexpected shower bath in sticky, bran-thickened milk.

It was aggravating, I must admit, and I am afraid that only the presence of Robert prevented the use of some rather strong language.

A moment later, however, a rotund face appeared in the barn door and a hearty voice inquired, "Any calves to sell?" Well, didn't that question fall pleasantly on my ears! I certainly had one calf that I would be only too glad to sell. I had almost reached a state of mind when I would have given the animal away.

"You can have this one," I exclaimed, breathless, as I wiped the cream out of my whiskers.

"How old is he?" was the next inquiry.

"Oh, old enough for veal," I answered.

"All right," the visitor said, a twinkle in his eye, "I'll give you $6 for him."

"The beast is yours," I responded, with fervor, and it was with a sigh of relief that I saw him disappearing down the driveway, the unfortunate captive bawling a lusty protest against the separation from the commissary department with which he had become so familiar.

It was some time later that I saw a neighbor teach a calf to drink by thrusting his fingers, moistened with the milk into the sides of the animal's mouth, and in that way gradually induce him to take nourishment. A little while after I tried the same plan, but not very successfully, and it was fully a year before I learned that if you allow a calf to get good and hungry it is a very simple matter to teach him to drink. I had been foolish enough to think that a calf had sufficient brains to acquire the habit by an intellectual process.—American Cultivator.

INDICATIONS OF PURITY.

In the matter of live stock mere color is too often taken as a guide in determining the merits as well as the price of the thoroughbreds, says the Philadelphia Record. When confined to thoroughbred poultry, where the markings have so much to do with the price to a fancier, the case is somewhat different, and it may be well enough to be governed to a great extent by those markings, or "points," laid down in the "standard;" but when considering the larger breeds of stock, —cattle, horses, etc., it is not the best policy to adhere too closely to any mere fashionable color or marking, for it does not alter the economic—the real—value one iota. No matter if a horse does have a "blaze face and three white feet," if he can trot low down in the teens and the would-be purchaser desires speed, a high price can always be secured for him. Even if a Jersey cow is "off color" and does not have the "black tongue and switch," provided she not only pro-

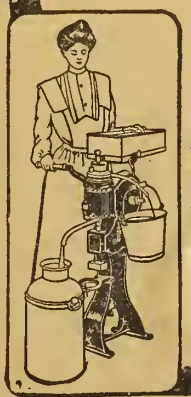
If you contemplate buying a machine let us show why ours is the simplest, easiest running and most lasting.
Separators can also be seen in operation on nearby dairy farms. Correspondence solicited.

YOUR MONEY BACK - QUICK
5 Cows and a U. S. made $45.00 month
7 Cows but no U. S. made $11.00 month
The U. S. makes the difference $34.00 month
STAUNTON, ILL., SEPT. 25, 1905.
I hereby certify that on April 20th, 1903, I bought of your agent one of your No. 7 U. S. Cream Separators, and after using it for more than two years, I am more than satisfied. In 1902 I sold the milk of my seven cows to the creamery and realized from said cows an average of $11.00 per month. From the herd in the spring of 1903 I sold two of the seven cows and milked the other five, and my income from the five cows was $45.00 per month, a difference of $34.00 in favor of the U. S. Separator. If necessary I will make affidavit as to this statement.
E. D. BRUCE.


Now, how quick did Mr. Bruce get his money back? Well, the *extra* profits alone paid for his U. S. in just about 10 weeks. Many thousands of satisfied users prove the

duces extra fine calves, but is an exceptionally good and heavy butter producer, she will always bring a good price if the owner can be induced to part with her, which is not often the case. To secure uniformity of breed characteristics it may be well enough to adopt certain marks and colors in some kind of live stock, but it is, and has been, carried to an extreme and in nothing more so than in poultry as well as in Jersey cattle. What should be desired is an animal bred for "business" first and after may follow the "fancy points."

IMPORTED MILKING GOATS.

The Department of Agriculture has imported from the island of Malta a herd of 68 milking goats. These animals have arrived at New York and are now in quarantine awaiting inspection. They will be taken to the Connecticut experiment station, where they will be fed, milked and propagated under scientific conditions. The young will be distributed throughout the experiment stations of the different States. In a statement, Secretary Wilson says:

"The milking goat has been neglected in the United States. Goats are almost entirely free from tuberculosis. Their milk is peculiarly adapted to children, resembling human milk more than that of any other animal. It is also valuable for invalids. People who cannot keep a cow may keep a goat."

The herd was selected by G. F. Thompson, a special agent of the department. The goats average about three quarts of milk daily.

SANITARY DAIRY LAW.

Editor Cultivator:—Will you give the text of the Sanitary Dairy Law as it was passed last winter. But more especially that provision which refers to adulterating milk.—G. B. S., San Jose.

The full text of the law is too lengthy for publication in these columns. A copy of the Act, Statutes of 1905, may be had by writing the State Dairy Bureau at Sacramento.

Section 4, of the statute, makes it an offense to use any compound in the milk containing salicylic acid, formaldehyde, coloring matter or any other chemical preparation other than salt or sodium chloride to prevent fermentation.

Neither shall gelatine be added to milk or cream, nor any other substance to make it appear better in quality or to give it a richer look. In the Cultivator this week, appears certain provisions of the law as construed by the State Dairy Bureau.

STATE DAIRY BUREAU ACTIVE.

About five months ago the State Dairy Bureau inaugurated a campaign among the dairymen of this State, to enforce the law created by the last Legislature entitled and known as the "Sanitary Dairy Law."

Prior to the passage of this act, the great majority of the dairies in California paid little attention to sanitary provisions. The law was enacted as an emergency measure and the inspectors were charged, upon appointment, with the duty of enforcing the statute.

Some of the dairymen readily responded to the notice to "clean up," but others do not. Now, the Cultivator is advised that prosecutions will be begun against every dairyman who fails to comply with the notice sent him, within thirty days from its receipt, to put his premises in order as the law provides.

In order that the dairymen throughout the State may understand just what is expected of them, the Cultivator deems it best to embody the construction of the law by the State Dairy Bureau. Those which relate to cleaning the dairy and surroundings are as follows:

* * *

The water used by the cows and otherwise in connection with the dairy must not be stagnant or in any way liable to contamination from drainage, manure, urine or decaying animal or vegetable matter. It should be pumped from a deep well located outside of cow yards, or otherwise located so that it may not become contaminated, or from a flowing uncontaminated stream.

The yard in which cows are kept must be free from mud or dust.

Manure must not be permitted to accumulate in cow yards.

Stables must be clean and as free as possible from manure, urine and other dirt.

Stables must be whitewashed at least once in two years.

No decaying food or other decaying or foul material must be allowed in mangers and feed boxes.

Milking pails, coolers, strainers and cans and all articles coming in contact with milk must be thoroughly clean, including sterilizing or scalding with boiling water or steam under pressure.

The body, and especially the hands, of milkers and others coming in contact with milk must be clean.

The clothing of milkers and others coming in contact with milk must be clean.

MANGEL-WURZEL AS FOOD FOR CATTLE.

What would be the relative feeding value of mangel-wurzels and golden tankard for cows testing about 5 per cent butter fat. Would stock sugar beets, as Lane's Imperial or White Silesian be better, and would the extra quality compensate for smaller crop and greater labor of harvesting?—L. B., Long Beach.

Answering the first of the above questions I would say that there is very little difference in the feeding value of the ordinary mangel-wurzel and the golden tankard, as the following analyses will show:

	Golden Tankard.	Mangel.
Water	91.98	90.90
Protein	1.40	1.40
Fat	.08	.20
Crude Fiber	.65	.90
Starch, sugar, etc	4.97	5.50
Ash	.92	1.10
	100.00	100.00

Doubtless different samples would show slight variations from these figures, but not sufficient to materially affect the relative value.

Prof. Roberts, of Cornell station, conducted an experment along the line suggested by the second question.

Five different varieties of sugar beets were used in the tests, one row for each variety, and three rows of mangels. The yield was as follows:

Five varieties of sugar beets averaged 23 tons to the acre.

Three rows of Long Red Mangels averaged 31 tons to the acre.

A difference of 36 per cent in favor of mangels, though one variety of sugar beets yielded considerably more than the mangels. Moreover it is twice the labor to harvest the sugar beet, so it would seem clear that if the roots are to be raised for feeding purposes, so far as the yield is concerned mangels are much to be preferred to sugar beets. Below is shown average composition of the sugar beets and mangels:

	Sugar Beets.	Mangels.
Water	85.05	90.90
Protein	1.12	1.40
Fat	.10	.20
Crude Fiber	.95	.90
Starch, sugar, etc	12.00	5.50
Ash	.78	1.10
	100.00	100.00

It will be seen that the main differences between the two lie in the water and carbohydrate content. The sugar beets being richer in sugar, and therefore weight for weight these have a higher nutritive value than the mangels, but the amount of total dry matter, as shown by the analyses, indicate that the yield per acre is practically the same for both feeds; the figures being 3.19 and 3.04 tons respectively. Again, sugar beets will, if fed in large quantities, tend to induce scouring. It would appear, therefore, from all the facts at our command, that the extra quality would not compensate for the smaller crop and greater labor in harvesting.—M. E. Jaffa, University of California.

Satisfaction or No Cost

The honest method of selling. We could fill this paper with testimonials of how Security Stock Food has made money for others. We prefer to prove what it will do for you.

Use **Security Stock Food** (glutenized) for growing animals; for fattening animals; for work horses; for milch cows. The Food won't cost you a cent if you can't see that **Security Stock Food** has saved feed, made quicker growth; kept your animals in better condition, given more milk, and made you more money. Write us if not satisfied and we will refund price in full. You are the sole judge. No questions asked.

For five years this guarantee has been on every package sold. It also covers Security Poultry Food, Lice Killer, Gall Cure, Colic Cure, Worm Powder, Calf Food, Heave Remedy, Healer and Rheumatic Liniment. Security preparations are sold by dealers in almost every town in the United States, who will recommend them highly and "back up" our guarantee.

SECURITY IS THE ONLY GLUTENIZED STOCK FOOD.

A Telephone for the Country Home

The telephone in the country home is not a luxury—it's a money-saving investment that brings returns every day. Keeps the farmer's family in close relation with the neighbors, saves many a trip to town, and helps to make the young folks satisfied with the farm by giving them advantages like their city cousins.

Stromberg-Carlson Telephones

Are the right telephones for country homes. They work right, *stay right*, and the price is right. Our new book 71-E, "How the Telephone Helps the Farmer," illustrates and describes how our telephones are made- explains why they are the best to buy. Farmers are building lines all over the land. *Why not you?* The book shows how cheaply it can be done. If you are interested we will send you a book telling "How to Build a Rural Telephone Line," and how to maintain it after it is built. Both books are *free*. Write nearest office for them *today*. Address

STROMBERG-CARLSON TEL. MFG. CO., Rochester, N. Y., Chicago, Ill.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

THE STORY OF A BEET COMPARED TO A HEN.

"Live and learn" has always been a favorite proverb of mine, and I am just now learning some things new to me which are so interesting that although they do not exactly bear upon the poultry business, will, I am sure, prove instructive to readers of the Cultivator.

I am visiting friends near Spokane, Wash. (I hope, however, to be home in Hollywood next week). My friends are seed growers, selling seeds by the carload lot or ton, carrots, turnips, peas, radishes, beets, etc., besides great quanties of seeds of beautiful flowers.

Their methods are (just like the progressive poultry breeders) to get the best seed to commence with and then go on improving that breed, or I should say, that kind.

The Government sends an expert to test their plants and seeds, and here let me say we can scarcely be grateful enough to our excellent Secretary Wilson, of the Agricultural Department, for the work done to promote the welfare of the farmers, and for the Farmers' Bulletins which are sent out to all who ask for them. I frequently advise our readers to send for some of them, especially the one on poultry foods, (Bulletin 164) issued at Berkeley, which can be had by sending a postal to ask for it.

* * *

The story of the development of one plant here, the sugar beet, is such a good illustration of the way to develop poultry that I am tempted to step down from our "feathery kingdom" and tell it as I, an outsider, see it, apologizing to the Agricultural Department of the Cultivator if I am trespassing.

About twelve years ago my friend to whom I referred above, sent to different countries in Europe for seed of the best sugar beets, the most sugary he could hear of; he wanted to find the beet that would produce the most sugar and would therefore pay the best in this country, just as we want the breed of hen that will produce the most eggs. These seeds he planted in separate colonies, each variety by itself, to discover which would produce the most tonnage to the acre, and also which contained the most sugar to the beet, just the progressive poultry man's plan.

At first there were no government experts here. Sample beets were sent to the Agricultural College to have the sugar contents analyzed, that he might compare the products of the different varieties. Some of the foreign seed he found well suited to this country, other seed not so good. He kept the best, and year by year he developed or bred up, as we should say, the best of the beets, so that from the beets which at first contained only about eighteen per cent of sugar he now has developed over twenty-six per cent. Fancy a beet more than one fourth of which is sugar!

I was attracted to asking questions by hearing something said about "the pedigreed beets." "Do you have "pedigreed beets?" asked I. "Yes, indeed," was the reply, "line-bred and pedigreed." "This is almost as interesting as the poultry business." "Well, now, let me tell you," said the beet breeder. "I can tell a high-testing beet by sight, just as you can tell a Standard-bred fowl; there is a great deal very similar, too, in the business. There is a difference in the texture of the leaves, whether fine or coarse, just as in the combs and wattles of fowls.; a difference in the way the leaves grow, whether upright or spread flat out, just as in the case of feathers on fowls, and then there is also the shape of the beet itself, comparing to your shape and carriage of fowls; and then there is the testing of the amount of sugar in each beet, just as you test the number of eggs laid by a hen, or as the farmer tests the butter fat in his cow's milk."

Another item of great interest to me, as a poultry breeder, is that the beet grown one year (a pullet) is tested (as we would a yearling hen's number of eggs) for sugar or saccharine content. This is done by taking a small piece out of the beet and analyzing it; if the test gives a high percentage that beet is labelled by the government expert with a copper label (as we would leg-brand a hen) and then is put aside to be planted in the spring for seed just as we keep over our best hens for two-year-old breeders.

These roots are planted the following year and kept as heads of families, and their offspring is kept year after year separate and is tested, some families becoming better and some deteriorating in sugar content or tonnage. Those that deteriorate are immediately discarded, the whole family being destroyed, just as the fowls should be.

The secret of success on this great seed farm is the thoroughness and painstaking used. My friend, besides being an expert himself, sent about eight years ago to France for an expert seedsman as foreman, and has spared neither money nor labor in developing the business on his several large farms.

One word more about the sugar beet. As I write I see from the window two huge fields, each containing over two million beets, grown only for seed, all grown with the utmost care.

* * *

The same energy used in building up a poultry plant, with the same methods and less capital would bring as great results, but the people think poultry raising so easy that they will not be as thorough or as careful, hence the failures.

* * *

Just as I close, a letter forwarded from the office of the Cultivator is at hand, from a lady who wants to know why she cannot hatch as many chickens in an incubator as a hen can. This is a very important matter, and a full answer to her letter may help others, so I will try to reply in next week's Cultivator as fully as possible.

CONSOLIDATED.

At the meeting of the Southern California Poultry Association last Tuesday evening, a propostition was made by the secretary of the old Los Angeles County Association, who was present, to surrender sufficient of the stock of the old Los Angeles County Association to give control of that organization to the members of the new association. This was practically accepted by the members present and referred to a committee or three to arrange the details of the consolidation, which it practically amounts to.

It is certainly hoped that this will be successfully carried through for the scrap which has been on since the termination of the old Los Angeles County Association show last January has not been to the advantage of the poultry industry of the southern end of the State. Besides, it has led to many statements, in print and otherwise, which have caused no little feeling and, at times, almost led to serious disruption on the part of old friends.

If the arrangements which were started on Tuesday evening are completed and the two organizations become one, it will mean a most successful show this coming January, instead of two, one of which would certainly have met with indifferent success. It has often been stated that the old association had the money and the coops for conducting a successful show while the new association had all the birds. Now the two together will insure the success desired. Mrs. Burbridge stated in her talk that the new arrangement would carry with it the tendering of her resignation as secretary and that she would be glad to affiliate and work for the new organization.

WHITE LEGHORNS
Eggs from pure white, trap nested, high-grade birds. Just a few cockerels for sale.

BUYS THE WORLD'S FAMOUS EGG FOOD NO. 4

MIDLAND

IF YOU WANT EGGS YOU WILL FEED NO OTHER

Used by all the largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Hap-hazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultrymen who have used these machines have supreme confidence in their ability to hatch and brood. Hence their ever increasing popularity. Winners of the GOLD MEDAL at the St. Louis World's Fair for greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1604.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A FILCHER, Commissioner.

And Now Comes New Reward for Merit:

Read the following telegram received from the Lewis & Clark Exposition at Portland:
"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clark Exposition."

Henry Albers LOS 315 South Main St. ANGELES

DEAR EXPERIENCE.

The Deacon, writing of his experiences in poultry raising, thus summarizes the merits of the different breeds of fowls which he has tried:

I have tried almost every practical breed represented in the Standard, and a few not in it.

The list includes: Black Spanish, Black Minorcas, Brown and White Leghorns, Games, Light and Dark Brahmas, Buff and Partridge Cochins, Langshans, Houdans, Barred and White Plymouth Rocks, Silver and White Wyandottes, Rhode Island Reds, and White Wonders.

The Black Spanish was my first love. I was then a boy, and in those days they did not breed a large white face. Now the exhibition Spanish are, in my estimation, the homeliest, most unattractive specimens I ever saw. They have large white faces, and that just put them out of business. You hardly can find anyone breeding the Spanish. What a pity. It was a breed that at one time commanded much attention, and they bore the distinction of being layers of the largest eggs. Like all heavy layers—breeds of the Mediterranean class—they lay a white egg. But when fanciers called for a white face—and the larger the better—they crippled both the egg yield and the size of the egg.

I believe the advent of the Black Minorcas in this country hurt the White Face Black Spanish more than it did any other breed. The Black Minorca is of the Spanish family, and was at one time known as the Red Face Black Spanish. I liked this breed very much, but I could not dispose of the carcasses to advantage. The market called for yellow skinned birds, and I could not get a good price for my white-skinned birds, which despite the best of care in dressing, showed the dark pin-feathers.

So I stepped over to the Leghorns, securing several pens each of the Browns and Whites. They gave me good carcasses and very satisfactory returns. The Browns laid the most eggs, the Whites the largest. The Whites being larger bodied, and as I could keep but one variety at that time, I got rid of the Browns, although I liked them very much.

The White Leghorns gave me the best of satisfaction, and I hated to give them up, but I had to for two reasons.

1st. They were such great flyers, giving me all sorts of trouble on that score.

2nd. The young cockerels were always in mischief, and kept me continually watching them.

Then I tried the Games—both the Black Breasted Reds and the Irish Belfast. They were excellent table poultry, but very poor layers, and, besides, were always fighting. Even the hens would fight like tigers—I got rid of them.

Then I took to the Asiatics—the Dark and Light Brahmas, and the Buff and Partridge Cochins. I soon dropped the Dark Brahmas, as the Light variety gave me more eggs, bigger eggs, and seemed to be more of a business fowl. I was disappointed in the Buff Cochins on account of their poor laying, and the lazy look that they always had. I found the Partridge Chochins better than the Buffs in every practical sense, but the Light Brahmas gave me the best results of all; and I kept on breeding them for nearly ten years, until this season, which I will explain later on.

About the time that I chose the Light Brahmas, I decided to add another breed, so picked out the Black Langshans. I found it an excellent laying breed, giving a finely colored egg, and doing grand work during the winter. For table use, on my own table, I was more than pleased with them, but my customers wanted a yellow skinned carcass, and I was compelled to get rid of my black beauties.

Then I tried Houdans. These gave me a large white egg, and proved very good winter layers; but I found them susceptible to colds, owing to the crest on their heads. If they became very wet they invariably took colds in some form or other. Then I took up Barred and White Plymouth Rocks. I dropped the Barred because they were so easily over-fattened. But when in good condition they were first-class layers. Their meat was more coarse-grained than I liked, and as they were dressed showed dark pin feathers, I made the change to the White variety. They were better in many ways, but still not exactly what I wanted.

Rhode Island Reds came in for a trial, but their mongrel look rather discouraged me. It was so hard to have hens match in color. They are good layers and good table fowls, but I was not pleased with the general appearance they made on the place.

The White Wonders I found satisfactory, but the fact that they belonged to the American class and had feathered legs, made me discard them. It is certainly un-American to give an Asiatic appearance to our home varieties.

Silver and White Wyandottes finally were tried, and I soon found that at last I had reached my ideal of a practical utility fowl. I chose the White variety, although I found the Silvers excellent. The dark pin feathers was the only reason that I had for not preferring them. I have now for several years bred the whites, and am so well pleased with them that I sold my Light Brahmas to make more room for my last choice. I have found them to be the ideal broiler and the most saleable roaster. I have found them to be second to none as winter layers, and by proper mating have got them to producing a good brown egg of a size equal to the Plymouth Rock.

I am giving these opinions more to show the beginner what he can expect in the different breeds.

Injuries sometimes cause undesirable feathers to appear. This is not necessarily an indication of a faulty bird, and may all come right when through moulting.

HOW TO DRESS DUCKS.

Feed them nothing twelve to eighteen hours before killing, says C. S. Gorman of St. Clair county, Missouri, an expert in killing and dressing ducks. Hold the feet and tip of the wings, and, with a sharp hatchet, or, best of all, a corn knife, cut the head off neatly, leaving the neck as long as possible. Do not drop the duck till it stops bleeding, and then some one should be ready to pick it at once. Pick all the feathers fit to save as quickly as possible. Put these in one box and the refuse from tail and wings in another. Do not bother with the last joint of the wings nor do not attempt to get all the down.

Try to have the feathers all picked while the duck is still warm. This done, have ready a liberal supply of paper; set this on fire and singe all the down that remains and the feathers under the wings and elsewhere, which are so hard to pick clean. The duck will be a brown, sooty looking object.

Nearly fill a large pan with water as hot as the hand can bear, put in plenty of soap to make a strong suds, and with a clean cloth wash the duck thoroughly, and all trace of the smoke is removed and the skin is beautifully

Standard Bred S. C. White Leghorns

POULTRY NOTES.

Kerosene is one of the cheapest and most effective insect destroyer for the poultry house. Use it freely and often.

Hens differ as much in laying eggs as cows in giving milk. Good cows produce good calves, good hens produce good layers.

An ideal henhouse should have plenty of glass windows through which the sun can shine. The house should be open on the south and closed on the north.

Heavy fowls should not roost on high perches. They hurt their feet when they fly down, and young fowls will strike their breast bones and injure them.

Fowls do not run together in large numbers. They will always divide into flocks of small size and will select different feeding grounds, always provided they have the opportunity.

A growing chicken, like a growing animal, requires plenty of good, wholesome food supplied liberally and often in order to enable it to grow and mature rapidly and to develop properly.

We note that one chicken fancier gives his young chicks nothing but sand and water for their first feed. When 24 to 36 hours old he gives corn meal and water. He feeds little mushy foods.

The top notch of quality in the demand for good poultry has never been reached. The demand for the best has never been supplied. There is no danger of getting it too good, but it often suffers from being off in quality.

Charcoal is an excellent thing for fowls, whether in confinement or running at large. It is inexpensive and so easily provided that no flock should be permitted to be without it. Let it be granulated and placed where the birds can readily have access to it.

In selecting the hens to be kept for breeders take those with small, smooth and neat heads, well-developed combs, bright eyes and nice tapering necks, long and deep bodies, active movements, vigorous in constitution and good layers, advises N. J. Shepherd, in Kansas Farmer.

Eggs in winter mean good prices and good profits, and one aid in securing them is to select the best of the early hatched pullets and the one-year old hens that moult early and keep them especially for the purpose, providing them with dry, comfortable quarters and feeding so as to keep in a good, thrifty condition.

The production of eggs is a great drain on the fowl's system, and during the laying season about one-half of the whole amount of nourishment taken into the fowl's crop is used in the production of eggs, and it is essential to see that they are supplied with plenty of the proper kind of food for egg production.

A flat perch is best, because of being more comfortable to the feet and best support to the breast when the chicken is sitting down. Arrange them far enough from the door to avoid a direct draft, on a level and not over three feet from the ground, and so arrange them that they can be readily taken down to be cleaned.

For swelled head and eyes in fowls a saturated solution of boraic acid applied with a soft sponge is one of the best remedies known. A teaspoonful poured down the throat twice a day is an excellent remedy for roup, while a mixture of equal parts of the powdered boracic acid and borax—a teaspoonful twice a day—is given as a good remedy for cholera.

While charred bones as well as charred corn is given poultry for the sake of the charcoal, which is wholesome for them, purifying the blood and aiding digestion, this charred stuff does not contain the food value of ground raw bone on account of the animal oils contained in the latter, which are consumed in the charring process. Fresh bones, when ground, are the most valuable, being full of animal matter.

The New Mexico Station says that there is no certain cure for cholera. Kill, burn or bury diseased fowls. Remove the well to new quarters, while the old resorts are often sprayed with a solution of one gallon crude carbolic acid to 20 gallons water. Use plenty of whitewash. In the drink put ½ teaspoon camphor spirits and ¼ ounce sulphocarbolate of zinc to one quart of water. Cleanliness is the great preventive. Symptoms are excessive thirst, yellow-green diarrhoea, ruffled plumage, etc.

WHY DOES A HEN CACKLE?

The reason commonly advanced is she wants to advertise her achievements to all the world. The Feather says that the cackle is a relic of long by-gone days when fowls were not domesticated and ran about wild. When a hen wished to lay she retired from the rest of the fowl community and performed her task. By the time she was ready to join the commonwealth the other members had wandered some distance and she did not know where they were. She waited till she had gone some distance from the egg, in order not to endanger it, and then she cackled, after also having taken a good look around to assure herself that no enemies were near. The rooster, hearing the cackle, answered it by a crow, and thus informed the hen of the whereabouts of the tribe. This sort of thing may be seen now among the ancestors of our domestic fowl in the Malay countries and India. Some poultry fanciers say that even now there are many cases in which a bird gets clear of the hen house and well out into the field before lifting up her voice. There is another point in support of the Feather's argument. When a broody hen, which is about to be set, or has been lately set, is alarmed, or discovers that she is in new surroundings, she frequently completely stops her cluck-clucking for a few minutes and cackles exactly like a hen which has just laid an egg. —Nor'-West Farmer.

* * *

[There is a chicken language that ordinary men do not understand. Close study would prove the hen that cackles because she is alarmed does not use the same chicken talk she does when she lays an egg. Other hens in hearing will join in the alarm call but never in the cackle of the egg-layer. Doubtless some domestic hens get a good ways from the nest before they cackle because they are ashamed of the size of the egg they have laid when eggs are 42 cents a dozen.]

The Board of Regents have stirred up a large-sized and active hornets nest by their announcement of the closing of the Tulare Experimental Station. The people of that section are organizing to put up a strong fight in the matter.

BY DR. W. J. OLIVER,
318 East Second St., Los Angeles.

To the end that this department may be made as valuable to the subscribers as possible, we ask observance of the following: Be sure to state in full the history of the case, location of the disease and the conditions under which the animal has been kept just before and since the disease ap eared. Give your name and address, which will not appear in the paper if you so request. No charge whatever is made for such questions as are answered through the colums of the Cultivator, but when an immediate mail answer is wished Dr. Oliver asks an additional fee of $1.00 and will give immediate attention and reply by mail. In such case write Dr. W. J. Oliver, 318 E. Second St., Los Angeles, Cal.

Questions should be in by Monday to be answered in the following Friday's paper.

BRUISED TEAT.

Editor Cultivator: About six weeks ago my cow began giving bloody milk out of one teat. sometimes once or twice in succession and then perhaps no more for a week or ten days. In the center of the teat there is a small lump about the size of a small pea. The lump is not hard nor very soft. She has had kind treatment and has not been hurt that I know of. She has had her second calf and will be fresh again in January.

If you will answer through the columns of your valuable paper I will be greatly obliged to you.—L. H. B., Lordsburg.

Your cow has bruised the teat, very probably in laying down or getting up. If you dry her up a month before calving which is the custom, nature may restore the parts. A little Campo Phenique rubbed in over the part twice a day will greatly assist. P. S.—Have teat perfectly dry when you apply it.

BLOODY MIK.

Editor Cultivator: What is the cause of a reddish liquid settling in the bottom of a milk pan after the milk has stood several hours?—J. J., San Martin.

Give a change of diet, and wash the udder with a good antiseptic, this destroys the micro-organisms on the surface. Give her 1 ounce Hyposulphite soda in feed daily.

ECZEMA.

Editor Cultivator: Can you tell me what ails my cow. The ailment began on her legs. It looks like wrinkles, which run half way round the back part of front legs; she will lick them until they will bleed. She has made a solid sore from her knees down to the first joint above he hoof. An examination of the raised places showed a thick mass of dried scurf. The disease has attacked her shoulders, at the root of the tail, and along the navel cord.—C. D. B., Long Beach.

Your cow has eczema. Wash thoroughly all affected parts and apply the following: Kreso Dip 3 ounces to quart of water, rub this into all effected parts every few days. Give internally in mash daily: Sulphur 1 1-2 pounds, nit. potash 1 pound. Mix Give tablespoonful each feed.

RHEUMATISM.

Editor Cultivator: I have a hog or shoat that has lost the use of his fore feet, or nearly so, can walk on them but would rather walk on his knees. It came on gradually, swellings like lumps have come clear to his hoofs and knees. Lumps are soft. I have bathed in hot water and soap and rubbed hard, but it did no good. What would you suggest. The hog eats well and is fat. Please answer through Cultivator.—W. D. G., Buena Park.

This is a rheumatic condition of the joints. Use the following treatment freely twice a day. Gum camphor 1 ounce, alcohol 8 ounces, witch hazel 8 ounces.

General Agricultural Notes

IMPROVING OUR WHEAT.

A great deal of attention is now being given, especially by scientists to the quality of California wheat, and we are told that it lacks in gluten and other desirable qualities, and that we can only hope to improve it by breeding a class of wheat containing more gluten, and state appropriations are eagerly sought by our scientists for this purpose. For nearly half a century California was the granary of the world. The wheat grown in this State was the best in the world; it contained gluten and every other desirable quality, the soil produced enormous crops, and the wheat farmers grew rich. For years the stubble was burned on the ground, the soil was plowed from three to six inches deep and the same land was cropped to wheat year after year, with continually decreasing yields and inferior grain. Now we are told that we must breed a new wheat suited to California conditions in order to restore our prestige as a wheat state. How would it do to try rotation of crops, deep plowing and fertilization, restore to the soil some of the qualities of which we have industriously robbed it until there is no more left? It might be cheaper and more effective than making big appropriations for scientists to produce new varieties.

NEW PLANTS FOR ARID REGIONS.

Dr. Fairchild, an agricultural explorer, and in charge of the work of introduction of new seeds and plants, says that the greatest surprises will be in the utilization of what are now considered desert lands, for the growing of special arid land crops requiring but a fraction of the moisture necessary for the growth of ordinary plants such as corn and wheat. "We are finding new plants," he said, "from the far table lands of Turkestan and the steppes of Russia and Siberia, which grow luxuriously under certain conditions of aridity that the crops of Mississippi valley farms would wither and die as though scorched by a sirocco."

Macaroni wheat affords a good instance of a crop that is capable of revolutionizing the values of tens of millions of acres of arid land.

"The macaroni wheat belt," said Mark A. Carleton, cereal specialist of the Bureau of Plant Industry, "extends, on an average, the width of the United States and from the 98th to well beyond the 102d meridian, with a general yielding capacity for half of this vast area of thirty bushels per acre, and of the other half of fifteen bushels.

"Macaroni wheat will grow with ten inches of rainfall and yield fifteen bushels to the acre, where ordinary wheat is an absolute failure. This is two bushels more than the average wheat yield of the United States. There are many other crops with as great possibilities and which thrive on but slight moisture, including splendid forage plants. I might mention Kaffir corn, the sorghums, millet, brome grass, as well as new kinds of oats and barleys of wonderful drought-resisting powers, the emmer or speltz and lots of others. We are constantly finding new grains and forage plants in the Caucasus, in Algeria, Turkestan and other dry countries which will bring under cultivation immense areas of the great American desert, now looked upon as absolutely unfit for agriculture. It is a somewhat singular thing that no men are as skeptical of the reality of these facts as the residents of this region, but our experiments have already proved what I have said to be actual facts, not theories."

Dr. Harvey Wiley, the agricultural chief chemist, says that the sorghums form a very fine stock feed, and that their cultivation along with the millets and other desert crops, where corn is an entire failure, insures a vast future development for that great section.

Improved methods of culture and tillage in connection with the planting of these hardy drought crops will change the face of nature throughout entire states.

INSTRUCTIONS CONCERNING FOREST FIRES.

Forest fires are almost always unnecessary. They usually result from failure to realize that carelessness will be followed by injury and distress to others. The resident or traveler in forest regions who takes every precaution not to let fire escape, and who is active in extinguishing fires which he discovers, contributes directly to the development and wealth of the country and to the personal profit and safety of himself and his neighbors. He who does not, assumes a great responsibility by endangering not only his own welfare, but that of countless others.

Care with small fires is the best preventive of large ones. The following simple rules may easily be observed by all:

1. Never drop burning matches or tobacco where there is anything to catch fire.

2. Camp fires should be as small as will serve.

3. Fire should not be built in leaves, rotten wood or other places where it is likely to spread.

4. Fire should not be built against large or hollow logs, where it is difficult to be sure when it is completely out.

5. In windy weather and in dangerous places, camp fires should be confined in holes, or by clearing all vegetable matter from the ground around them.

6. A fire must never be left, even for a short time, before it is completely extinguished.

7. Except as specifically permitted by law for logging redwood or back firing, fire or explosives must not be used to clear land during the dry season without permission from an authorized fire warden.

8. No engines or boilers using fuel other than oil may be operated near forest, brush or grass lands, unless provided with spark arresters and fire box protectors.

The last three of the above rules are law, and their infraction are directly punishable. Failure to observe the others will be considered willful negligence, should the fire escape and spread.

Any person discovering a fire too large to be put out at once, should immediately seek help in the vicinity, and, if necessary, notify the nearest fire warden. If no fire warden is available, the local justice of the peace, constable or road overseer should be called upon. All of these officers are authorized to call upon able-bodied citizens for assistance. Failure upon the part of any person who allows a fire to get beyond his control to take every practical step to secure assistance will be considered willful negligence.

The best tools for fighting fire are the shovel, mattock and ax.

If possible, a fire should be stopped or checked by plowing, trenching, or the use of earth; but if this is impracticable, back-firing may be resorted to. The use of back fires is attended with danger of useless burning and loss of control, therefore they should never be set by inexperienced persons except in great emergencies. If a fire warden can be reached in time, such measures should be left to his judgment; if not, and the fire is large, an experienced leader should be chosen to direct the work, and his directions followed, so that there may be no loss through unorganized effort.

Back fires should always be set from a road, stream, cleared space or natural fire line. Since fire rushes up hill, and is checked by air currents at the crest, and usually works down hill slowly, it should be attacked from the top of a ridge if possible. If it is burning down hill, endeavor to meet it before it reaches the bottom. If it is working up hill rapidly, it seldom pays to try to stop it before it reaches the top.

The night or early morning hours are the best time to work, when any choice exists, for nearly all forest fires die down more or less at night and spring up during the heat of the day.

Never trust a fire which is smouldering or "under control." Continue work until it is out, if possible. If not, watch it closely for fear wind or drying weather will cause it to break out again.

Protect valuable timber rather than brush or waste.

Young trees suffer more from fire than old ones.

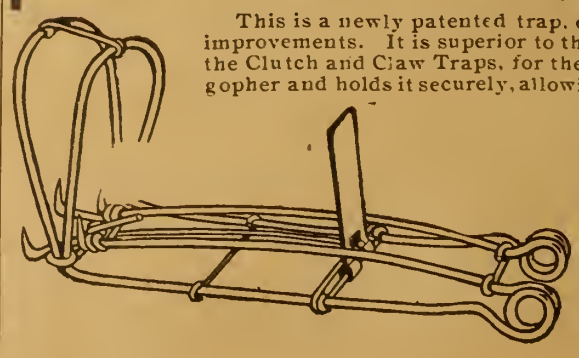
J. A. W. GATES, 216-218 West Second St. Los Angeles, Cal.

TRAPPED TO STAY TRAPPED
The trouble with most gopher traps is that they permit the rodent to escape after the trap has been sprung. This not only makes the old style traps worthless, but prevents the recapture of the gopher. The only sure means of destroying gophers is with the
Improved C. V. 2-Ring Gopher Tra


This is a newly patented trap, embodying all the latest improvements. It is superior to the Single ring, as well as the Clutch and Claw Traps, for the double ring disables the gopher and holds it securely, allowing no chance for escape.
See that you get the genuine Improved C. V. 2-Ring. Sold everywhere for 25c; or if your dealer does not have them, send us his name and 25c for sample trap or $2.50 for a dozen, which we will forward postpaid.
Falls Manufacturing Co.
14 Drumm St., San Francisco

U. S. Department of Agriculture, Climate and Crop Bulletin of the Weather Bureau, California Section, for the week ending Monday, Oct. 23.

General Summary.—Dry and generally clear weather prevailed during the past week, except light showers along the southern coast on Saturday and Sunday nights. Light frosts occurred quite generally in the northern portion of the State on the 18th and 19th, but caused no damage. Throughout the interior of the State the conditions were excellent for fruit drying and raisin making and rapid progress was made with both. The raisin harvest is now nearly all over in all districts; the yield was good and the quality excellent. Citrus fruits are making good growth in all sections. Oranges are developing rapidly and promise a large crop of superior quality. In portions of the San Joaquin valley they have begun to color.

Large shipments of Tokay grapes continue from the American river district. Wineries are generally running to their full capacity. The apple crop will be large and of good quality. Walnuts are maturing slowly in the southern part of the State, and the harvest has commenced in San Luis Obispo county. The crop will be good. The bean crop is nearly all harvested, and is large and of good quality. In the San Diego district the yield of guavas is excellent, and is superior to that of last year both in quantity and quality. The honey yield is good.

Plowing and seeding are progressing in the northern part of the State. Dry feed is plentiful in the San Joaquin valley, but getting poor in other districts. Stock are healthy and generally in good condition. Rain is badly needed in all districts.

Eureka Summary.—The weather was dry and clear with frosty mornings. Plowing continues and some seeding is in progress, but the ground is getting dry and rain is much needed. Large shipments of apples and peas continue.

Los Angeles Summary.—The weather during the week was cool with light rain at the close, but no damage reported. Bean threshing is nearly ended; some Limas yet in the field; the crop is good. Walnut harvest is in progress. Oranges are reported in some sections fine, but a light crop.

HENS THAT LAY.

Mrs. D. F. Stoner, of Ontario, has her announcement in this week's paper in which she refers to thoroughbred Single Comb White Leghorns. Mrs. Stoner has several pens of very fine appearing birds, which she is already mating up for the season's business.

IT BRINGS THE CUSTOMERS.

Cultivator advertising pays. Why not try a small advertisement when you have anything to sell, or if you wish to buy. Here is the experience of one advertiser (and we have more letters of similar expression) whose advertisement paid:

Pasadena Cal., Oct. 21, 1905.

California Cultivator Company: Last week I sent in an advertisement for my son (F. S. Lee) for sale of strawberry plants and on Tuesday last it brought us a customer for 32,000 plants. We will have to change the ad as Brandywine plants are about all gone. I send another advertisement today for sale of a Compton ranch. Please insert in an inch space until ordered out. Respectfully, C. F. Lee.

LOTS OF IRRIGATING PIPE.

While at Dolgeville recently we called at the office of the Tallerday Manufacturing Co., and we were informed that the works are up to their limit in manufacturing of the surface irrigation pipe which while comparatively new in irrigation has become very popular as a water saver. While this is nearly the end of the season, the works were well up to their limit and were even behind with orders.

In addition to the surface irrigation pipe which is made of comparatively light galvanized iron, this company makes large quantities of heavier weight black or dipped pipe for water conducted underneath the ground.

DOKE'S FOODS.

Those who have used the Doke Stock Foods are very pronounced in their commendation of that article especially where it has been tried in dairies. It is not a stimulant, but contains elements which keep the cows in the best of condition so that all foods are more quickly and more properly digested.

Regarding its use in dairies, Mr. Doke tells us that within two or three weeks from its taking, most pronounced results are observable and that increased quantities of milk and butter are secured. For cows that have aborted, feed same dose scalded in the bran, if fed regular and stock is well cared for, they will become strong healthy animals, producing their regular amount of milk. It is also excellent for poultry, a tablespoonful of it being sufficient for a feed for a dozen laying hens.

AS BRIGHT AS THE STARS.

Everything that labor, thought and modern equipment can do has been done to bring the Star Oil Burner to a high standard of perfection. The Star Oil Burner stands upon its own merits. It has been thoroughly tested, and has no superior for safety and economy. It generates its own gas and gives a fire "as bright as the stars." By using this burner you save 25 to 40 per cent over wood or coal. Call and see this burner in operation at the Western Star Mfg. Co., 148 W. Fifth street, or write for circular.

The Toluca Nursery has a supply of grafted walnuts on both the native black walnuts and English walnut roots. We do not know that there is any choice. We have heard it expressed that the native black root will make the hardier tree and one less liable to disease. In any case, Mr. Tosetti says, he has not only the black, but the English root for those who wish it, and will also supply the Santa Barbara soft shell seedling.

Besides these, he has a supply of Crandall Blackberries, Brandywine Strawberries and Logans. For information on these lines, write G. Tosetti, Toluca, Cal.

ORPHANS RECEIVED.

The following named children have been admitted to the Boys' and Girls' Aid Society of South Pasadena, Cal., since the last report:

Jewel Sternberg, Ger., half orphan, light brown hair, light brown eyes, 8 years old; Marian Sternberg, Ger., half orphan, blonde, 2 years old; Albert Williams, Eng., half orphan, brown hair, blue eyes, 8 years old; Bruno Yimez, Mexican, orphan, black hair, black eyes, 9 years old; Louis Yimez, Mex., orphan; black hair, black eyes, 8 years old. Lucia Yimez, Mex., orphan; black hair, black eyes, 2 years old. Emil Stern, Ger., half orphan; brown hair, blue eyes, 11 years old. Laura Higuero, Mex., half orphan; black eyes, black hair, 12 years old. Nora Manes, Amer., half orphan; blonde, 12 years old. Georgia Manes, Amer., half orphan; blonde, 9 years old. IF I CAN LIVE.

If I can live
To make some pale face brighter, and to give
A second lustre to some tear-dimmed eye,
Or e'en impart
One throb of comfort to an aching heart,
Or cheer some wayworn soul in passing by;

If I can lend
A strong hand to the fallen, or defend
The right against a single envious strain
My life, though bare
Perhaps of much that seemeth dear and fair
To us of earth, will not have been in vain.

The purest joy,
Most near to heaven, far from earth's alloy.
Is bidding cloud give way to sun and shine;
And 'twill be well
If on that day of days the angels tell
Of me, "She did her best for one of Thine."

—Helen Hunt Jackson.

Father's Sweetheart

When Miss Morrell came to look at the house next to ours she seemed quite nice. She smiled very pleasantly when she asked for the key; and while she was down in the garden she picked some apples and threw them over to Bob and Tommy. They were not her apples, really, because she had not taken the house; but I thought it was kind of her. So I called when she moved in. Mother is dead, so I have to call. Father is Frank Marchant, the celebrated author, and I am Molly. I was fifteen in June, and Miss Morrell was thirty-one, she said. She must have meant forty-one, because she and father were boy and girl together, she told me; and he is forty-three.

"He was such a nice boy," she said. "He'd have done well if he hadn't been so clever, poor fellow!"

"If he wasn't clever, he couldn't write his stories," I pointed out.

"What's the good of writing stories if you can't sell them? Clever men have no sense."

I am afraid that is true, but of course I would not say so, and I got up to go.

"Father is more than clever," I told her. "He is the best man that ever was, and the kindest. I will not listen to anything against him; and I think perhaps it would be better if you did not call."

I know it was not polite to say that, but even mother was not polite if anyone spoke against father.

Miss Morrell only laughed and took hold of my arm.

"Tit—tut, child! I think well enough of your father. I fancy he has a very good little daughter, too. Now sit down and have another tea cake."

They were ver nice tea-cakes, and she made them herself. She gave me the recipe, but mine did not turn out the same.

She was watering her flowers when father walked down the garden after tea. He did not notice her because he was worried about a plot. He had found a way of getting the hero and heroine off a precipice, but he could not think how to get them on! She came and watched him over the wall. She had the water pot in one hand and some weeds in the other, and she wore an old hat like a black basin.

"Still up in the clouds, Frank?" she called at last. He started and turned around. Then he held out his hand and laughed.

"Mary! Well I never!—It's good to look at you again!"

I did not want to listen, of course; and Dick was whistling at the front gate, so I went out with him. (He is Dick Carson, and we are chums. He is not silly like other boys.)

"I don't care for that woman," I told him; but he only laughed and said I needn't be jealous. He is an impudent boy. We went round by the lane and came home across the brook. It was quite dark when we got in. Father was still talking to Miss Morrell over the wall, and hadn't made the boys do their home lessons; and they were watching out of the window.

"Father's got a sweetheart, Molly," Tommy said.

I do not often lose my temper with the boys, but I boxed his ears quite hard. I was sorry directly, but I could not say so for fear I should cry. So I went up stairs to take off my hat. When I came down, Dick had Tommy on his knee, doing his last sum. There were white smears on his face where he had cried, and I wiped him with my handkerchief.

"Dick's given me a penny, Molly," he said, and grinned at me. He is a kind little boy and never bears malice.

Dick didn't look at me, and I thought he was cross. I did not get up to go to the door with him, but he tilted me out of my chair, so I had to go.

"Oh, Dick!" I told him. "I wish I hadn't"

"Nonsense," he said. "It will do him good, the little wretch. You didn't hurt him."

"No—o; but he was mother's baby, and—and——"

I think I should have cried, but Dick was so nice to me, and said I was good to the boys. I gave them four chocolates each, and read a chapter out of Swiss Family Robinson to them, when they were in bed; and Tommy said he hardly felt it, and only cried to frighten me. I don't think I did it very hard.

When I came down stairs father was sitting at his desk, but he was not writing. He did not speak till he caught me looking at him. Then he sighed.

"It has brought back the old times," he said. "We were boy and girl together—some day you will look back to the times when you and Dick were boy and girl together."

I did not say anything, but went into the drawing-room. If it had not been father, I should have told him not to compare that woman with me.

At supper he talked about her again. She was always bright, he said, and very pretty when she was a girl.

"People alter a good deal as they grow older," I remarked. "I don't know if you noticed her hat?"

Father laughed.

"The hat is not fascinating, certainly," he agreed. I thought he laid too much emphasis on "hat."

The next evening they talked over the wall again. The evening after he went to see her. He took a bundle of Mss. He never shows his Mss. except to literary people or people he likes very much.

The next day she sent us a dozen tea-cakes. Father ate two and the boys the rest. I offered Jane some, but she would not touch them.

"Not if I was starvin' an' a bite would save me!" she said. "I've got eyes in my 'ead, Miss Molly—she'll never do by 'em as you've done."

Jane forgets and breaks things, but she is a good girl really.

The next afternoon Miss Morrell asked me to take the boys in to tea. I told her I was too busy; but the boys wanted to go, so I let them. They are not old enough to know better. She gave them three sorts of cake for tea, they said, and sixpence each. She helped them with their lessons, too; but I found a mistake in one of Bob's sums.

"Ah," father said, when I showed it to him. "She never was good at arithmetic; but she has a wonderful head for business."

"I'd rather be good than good at business," I told him.

Father smoked his pipe for two or three minutes. Then he laid it down.

"She is good, too, Molly," he said. "I could tell you something—I will tell you, because I want you to like her. She was in love with a man once—they were only boy and girl, really—and he was in love with her. There was a misunderstanding, and he went away, and got engaged to some one else. One day he came back—and found out what a foolish mistake he had made. He would have broken the engagement off, but she wouldn't let him. So he married—the other woman."

I could have screamed to hear him speak of mother like that; but I bit my lip instead.

"If I had been the—the other woman I wouldn't have wanted him, if he hadn't wanted me."

"She didn't know, dear. She never knew, right up to the time that she died."

"You—he pretended he liked her all the time?"

"He did like her. She was a nice woman—a very nice woman, only—you will understand, dear, when you are older."

"I understand now," I said. My—his wife is dead. So he will marry Miss Morrell."

"I don't know." Father filled his pipe slowly. "I hope so. If he does—"

"It will serve him right," I declared. Then I went down in the shrubbery and cried.

"If ever you like some one else better, Dick," I said, when I told him, "you're to tell me. I wouldn't marry you for anything, if you didn't want to. Promise me—No, no! It's no use saying you never will, because you can't be sure—promise me."

Dick looked very serious and whistled to himself for a long time. He does that when he is thinking.

"I believe you are right, kiddie," he said at last. "I promise."

"On your honor?"

He threw his head back a little.

"All my promises are on honor," he said. I do like to hear him speak like that.

I did not say anything more to father about Miss Morrell; but I made what we called "mother's cake" for tea, and put all her photos about the rooms to remind him of her. He took up the one where she is holding some music, and looked at it for a long time.

"She used to sing a great deal at the Morrell's," he said. "Mary used to accompany her. We must ask her in. She will like to hear you sing some of the old songs."

"I don't want to sing mother's old songs to anyone but you, daddy," I said. "Come and play for me, and I'll sing 'Afterwards.' You can put it down a note and think it is mother singing."

People say that my deep notes are like mother's, but of course I do not sing as well as she did.

"You can't sing that just like your mother, dear. Thank Heaven! You can't feel it quite like she did—Ah!"

"I'll try to feel it as much as I can. No, in E-flat, dear." He nodded and played the symphony softly. It is like a dream, and father plays so beautifully. I thought of mother, and took a deep breath, and began:

"Beyond the bound of land and sea,
Beyond the touch of hand;
Beyond the memory of me—!
I shall look down, dear love, and see
Your tears; and understand."

She is supposed to be dying. The first part is what he says to her, and the second part is what she says to him. Mother used to smile when she came to "understand;" and father used to look over his shoulder and smile at her.

"Light of my life, if I should miss
The path your faith has shown?
My heart was heartened by your kiss,
But now—Dear love, be sure of this
You will not walk alone."

He is in the minor, of course, and she answers in the major. It always sounded comforting, the way that mother sang it; and when I am worried about things, I try to fancy that I hear her. Then she used to

The Star Oil Burner

draw herself up for the last verse.

"I shall look down, my dear—my dear!
Look down and smile on you.
Only be true and have no fear.
Only be true; and Heaven is near!
God judge me as I'm true."

I tried to steady myself and make my voice like mother's, and I seemed to see her standing there, with her hand on father's shoulder, and putting out her other hand to hold mine, when I was little and clung to her skirts. I took the low note in the last line quite full, and then something seemed to clutch my throat; and the big photo of mother that I had put on the piano slipped right down on father's hands; and I shrieked and shrieked and laughed and cried, and father couldn't stop me anyhow. I suppose you would call it hysterics.

I was better next morning, but Jane made me have breakfast in bed. Father was very worried because he was going away to Scotland to do some descriptive articles for the Daily Lyre. He began to write out a telegram to say that he couldn't go; but I told him that I was quite well, really, and Jane promised to look after me "like a mother." So he went.

When he said good-by, he gave me a note for Miss Morrell. "Ask her to wire 'yes' or 'no;' then I shall know what to do," he said. "Good-by, dear old girl. Be sure to telegraph if you want me back."

It is a dreadful thing to say, but I felt as if I never wanted father back again. If I hadn't loved him so, I believe I should have hated him. You would understand if you had no mother.

I told Jane about the letter, and she said anyone could tell it was a proposal; and if she was I, she would burn it. I was a good mind to, but when I asked Dick, he said, "it wouldn't be straight." So I gave it to him to do what he liked with it, and he took it in to Miss Morrell. She asked him to take a telegram to send off to father, but he told her he would rather not have anything to do with it. He saw her write it, and it was "yes!" He wouldn't look at me when he told me, but he said a lot of nice things about me and how good I was to father and the boys, and I shouldn't have to live with her very long, because he was growing up. I think anybody would like Dick. He is so kind. Jane was very kind, too, and didn't even grumble at Bob when he knocked over a pail of water.

"I'd have liked to box 'is ears!" she said, "but but I thought of you, you poor dear—more'n a mother you've been to them; and 'e ought to be ashamed of 'isself, the master ought."

In the afternoon I sat down in the garden darning the boys' socks, and Miss Morrell came and stared at me over the wall. "You don't look well, child," she said. "I am quite well, thank you," I told her. She put up her eye-glasses and looked at me. "You're too young to look after a house," she said abruptly. "Anyhow," I said, "I have looked after it. I don't suppose I have done very well, but I have done my best. No doubt you could do better; but you'd find it very different from having only yourself.' I thought that I would let her see that I understood.

"I daresay I should." She sighed; but she did not seem cross. "Do you know, Molly, sometimes I wish I had others to work for. Don't you think I could help you?"

"I don't want any help," I said; "and if I did, I'd rather not have it. You see I promised mother. She wouldn't want anybody else to do things for father and the boys—only me." I looked straight at her, and she shook her head.

"We were children together," she said, "she and your father and I. I don't think she would mind me."

I gathered up the socks and angola together and got up.

"I think," I said, "she would mind you very much."

Miss Morrell looked surprised and hurt.

"You don't like me, Molly," she asked.

"No," I told her, "I don't. You have sent the telegram to father, I suppose?"

"Yes—your father has told you?"

"He has told me." It was not true; but I could not let her think that father did not trust me. "Good-afternoon."

I went indoors and gave the boys their tea. After tea I gave them two pennies each to spend. I thought I should not have the housekeeping money for long; and she would not do things for them like mother used to, and like I tried to do.

Father came home on Sunday night. He had only just taken his hat off and sat down in the arm chair when she came in. He jumped up and held out both hands; and she trembled and half laughed and half cried. She looked quite young and almost pretty; and I hated her.

"I am so glad, Mary," father said. "So glad, dear old Mary. God bless you!"

"God bless you, Frank—kind old Frank!" she said. Then she began crying softly; and he bent down and kissed her. I was in the dark corner by the screen and they did not seem to notice me. I felt my heart thump and my breath come and go; and I looked at them, and looked at the big photo of mother on the mantelpiece. It was just beside them, as if she was watching them; and I rushed between them and snatched it away.

"Mother!" I cried. "Oh, mother!" Then I seemed dizzy and tripped over something; and Miss Morrell caught me, and I didn't remember anything more till I found her bathing my forehead with eau de cologne, and I was too weak to push her away.

"My poor child," she sobbed. "My poor child!" Her tears fell all over me, she was crying so. "We ought to have understood. It isn't your father, darling. It's my old lover that he has found for me in Scotland. That was what I telegraphed about. Now, we'll see if you can't like me a little—No, no! You musn't move yet." But I sat up somehow and held out my arms to father; and he picked me up and nursed me like a baby.

"I've only two sweethearts, darling," he said, and he wiped his hand across his eyes; "your mother—and you."

I shall never quite forgive myself for thinking of him as I did, but it was only because I was so fond of mother.—Owen Oliver in Delineator.

DO YOU KNOW

That if you rub grass stains with molasses they will come out without difficulty in the ordinary wash?

That spots may be removed from gingham by being wet with milk and covered with common salt? Leave for an hour or so and rinse out in several waters.

That sheep sorrel will take out rust stains from cloth? Rub thoroughly on the stains, and then take out the resulting grass stains with either molasses or alcohol.

That you can make a faded dress perfectly white by washing it in boiling cream of tartar water?

That salt dissolved in alcohol will often remove grease spots from clothing?

That mud stains can be removed from silk if the spots are rubbed with a bit of flannel, or, if stubborn, with a piece of linen wet with alcohol?

That two potatoes granted in a basin of warm water give better results than soap in washing delicate flannels or woolen goods, ribbons, etc.?

That linen blinds can be cleaned by laying flat and rubbed with powdered bath brick?

That carpets and rugs can be thoroughly cleaned by being hung over a clothes line and having the garden hose turned upon them? This will do no harm to any carpet. Dry in a shady place.

SLEEPING CHILDREN.

Editor Cultivator:—Should children sleep in separate beds?—H. I. N., Ventura.

As far as practicable each child should have its own bed, during warm weather, especially. No two children are constituted alike and each requires a different weight of clothing. The child of nervous temperament rests best alone. Care must be taken to have the covering light and warm. The sleeping room should always be properly ventilated. By this we mean plenty of fresh air, without draught over the bed.

STUDY HIS MIND.

Editor Cultivator:—I have a boy who will not go to school without forcing him to do so. He prefers to spend his time reading novels. What shall I do to awaken his interest in his school?—Mother, M. C. H., Oakland.

If you will try and learn what class of novels your boy reads, you may get the bent of his mind. If they are historical in character or along the line of ornithology or any of the animal studies, cultivate his taste. If he is reading trash, you will have to interest him in books of animals, birds or travels. His teacher ought to be able to assist you in directing the trend of his mind. Perhaps the trouble is in his teacher? Maybe in yourself. Try and find where the fault is and you can the better apply the remedy.

Cookery Recipes

A FAMOUS RECIPE FOR CHILE SAUCE.

Fifty good-sized ripe tomatoes, scalded and skinned; twenty-five onions of medium size; eighteen green peppers, seeds removed; two bunches celery. Chop them all up quite fine, add three cups granulated sugar, four tablespoonfuls salt and one tablespoonful each of ground mace, allspice, cloves and cinnamon, with two quarts of cider vinegar; put them all in a granite kettle, cook slowly for three hours and stir often to prevent the mixture from sticking to the bottom of the kettle. When cool put up in bottle, sealing well until needed.

* * *

ICED COFFEE.

Prepare your coffee as for the regular meal, with or without milk. Pour in glasses half filled with ice, with sugar to taste.

* * *

WINE WHEY.

Sweeten one pint of milk, or more if you desire, and boil it. While boiling add two or three wine glasses of sherry. When the curd forms strain the whey through a strainer into the glasses.

* * *

PINEAPPLEADE.

Pare and slice some ripe pineapples; then cut into small pieces and put them with all their juice into a large pitcher. Sprinkle them with plenty of powdered sugar. Pour on boiling water, allowing a small half pint to each pineapple. Cover the pitcher and let it stand until cool, occasionally pressing down the pineapple, to get the strength of it. Set the pitcher for a short time on ice.

The Rhode Island Station conducted an interesting experiment with an incubator hatch of 219 chicks. They were put into lots of about 50 each, and placed in similar brooders. For thirty days all conditions were kept alike except rations. Pen A was fed a balanced ration of grains, meat and green food. Pen B had grains and green food, Pen C had grain alone and Pen D received only meat and green food. The percent of deaths in order of pens was 4, 9½, 33 and 76½. Those in last three pens died almost entirely from bowel troubles. Pen A had no bowel troubles and the survivors showed the best average weight. This shows that outside of brooding and incubation chicks may be killed by improper feeding. The animal meals of commerce are handy, but a cow's liver cooked slowly, till crumbly, and shopped fine, has gone a long way with my flocks.

WELL DRILLING MACHINERY

Portable and drill any depth by steam or horse power. 42 Different Styles. We challenge competition. Send for Free Illustrated Catalog No. 13.

Kelly & Taneyhill Co

Honey and Beeswax.

HONEY—New crop, Comb, per lb., 10@12c; Extracted Water White, 6c; Light Amber, 5@5½c; Dark Amber, 3@4c; Hawaiian, 2@2½c.

BEESWAX—Per lb, 26@28c.

Beans and Peas.

BEANS—Prices per ctl: Large White, $2@2.40; small do, $3@3.25; Pea, $3.25@3.75; Lima, $3.40@3.50; common shipping points, $3.20; Red, $3@3.50; Pink, $1.75@2.15; Bayos, $3.50@3.75; Blackeyes, $4.40@4.60; Red Kidney, $3.50@4; Horse Beans, $1.25@1.75.

DRIED PEAS—Prices per ctl: Niles, $1.75@2; Green, $1.75@2.25; Field, $1.50@2.

Live Stock.

Conditions throughout all departments of the Live Stock market are purely a reflection of the features thoroughly reviewed for some time past. Sheep continue in scant supply and rule strong at full quotations and A1 Steers and Lambs share second place interest at firmly held rates. Calves and Hogs are plentiful at the familiar prices.

CATTLE—No. 1 Steers, 6½@7; second quality, 5½@6c; third quality, 5@5½c; No. 1 Cows and Heifers 5@5¼c; second quality, 4½@5c; third quality, 4c; thin Cows and Heifers, 3@4c; Bulls and Stags, 2@3½c. Prices for all descriptions less 50 per cent shrinkage.

CALVES—Light, per lb, 4¼@4¾c, gross weight; medium, 3¾@4c; heavy, 3½c gross weight.

SHEEP—Per lb: Wethers, No. 1, 3¾@4¼c, gross weight; Ewes, No. 1, 3¼@3¾c, gross weight.

LAMBS—Suckling, $2.75@3.25 per head or 4½@5c per lb., live weight.

HOGS—Per lb.: Hard grain fed, weighing alive 80 to 130 lbs., 5¼c; 130 to 250 lbs, 5½c; 250 to 350 lbs., 5¼c; rough heavy, 4@4¼c; common, 3½@4c.

Hay and Cereals.

HAY—Per ton: Wheat, $11.50@16.50; Wheat and Oat, $11@15; Oat, $8@12; Barley, $8@11; Clover, $7@10, Alfalfa, $6.50@9.50; Stock, $5@7.

WHEAT—No. 1 Shipping, per ctl., $1.30@1.35; inferior grades, $1.15@1.30; White Milling, good to choice, $1.35@1.45 for new and higher for old.

BARLEY—Choice No. 1 Feed, $1.13¾@1.16¼; some fancy grades up to $1.17½; common to fair, $1.10@1.12½; inferior grades, $1.05@1.07½; Shipping and Brewing, $1.17½@1.20; Chevalier, $1.20@1.30.

OATS—Good to choice White $1.37½@1.45; Red, $1.35@1.50 for choice to fancy; $1.15@1.32½ for common to fair; Black for seed, $1.60@1.75; lower grades, $1.25@1.55.

RYE—Good to choice, per ctl, nominal; new, $1.45@1.52½.

CORN—Good to choice, per ctl: California, new, large, Yellow, $1.45@1.50; small do, $1.60@1.65; White, $1.40@1.45; Eastern Yellow, $1.40@1.42½; White, $1.40@1.42½; mixed, $1.35@1.40.

CITRUS MARKETS

High prices have been received in all Eastern markets this week, with supply light and buyers eager. Floridas are coming in better condition and commanding higher prices.

New York.

Two carloads of Valencias were offered Friday in a driving rain, but the demand was keen and prices firm. Old Mission brand averaged $8.72 for fancy, while Colton Terrace ex fy, averaged $5.38.

Three cars of oranges and three of lemons were offered Monday and all went at good figures, quality considered. Oranges ran from $1.35 to $6.17 per box, while lemons averaged $7.00 for ex ch.

Two cars of Valencias were offered Tuesday, ex fy averaging $8.75. ch $5.15 to $7.40 and standards $6.30 per box.

Four cars of Valencias and one of lemons offered Wednesday. Fancy oranges brought $8.37 on an average, while lower grades ranged from $6.45 to $4.91. Lemons were steady around the $5.00 mark.

Chicago.

Lemons were in fair demand Friday, with shipments on the way. Sound stock sold as follows: 360, $5.25@$5.60; 300s, $5.60@5.85; 240s, $5.25 up; 420s, $5.50 up. Oranges in light supply and bringing $5 to $6.50.

No change in lemons Monday and California oranges are also scarce, bringing $5 to $6.50 per box.

Wednesday brought few oranges, and they were firm at $5.00 to $6.50 per box.

Boston.

One car of late Valencias at Friday's auction brought from $2.75 to $5.75 per box under a keen demand.

No citrus fruit offered here the early part of the week.

Total Shipments.

The total shipments of citrus fruit this season are 29,556 cars, of which 4373 were lemons.

THE REDDEST ROSE.

Among all the flowering shrubs that grace the garden or add to the beauty of hall or conservatory, none can compare to the rose. Of diverse color and character of foliage, of endless design and color of blooms, it lends itself to a wider range of decoration than any other single group of plants, being equally desirable as pot plants, garden culture, and for cut flowers. When to these qualifications are added ease of culture and quick and ample responses in flowers, it is explained why the rose has been aptly termed "The Queen of Flowers."

In our illustration is shown Grus an Teplitz, one of the most popular of the newer roses, being of the deepest possible red when in the bud, when opening becoming more brilliant and fiery. Easy to propagate, easy to grow, it will always be a strong garden favorite.

GRUS AN TEPLITZ Courtesy Armstrong Nurseries

CIRCULATION EXCEEDING 11,600

You You Yours

Your Business to Consider

A ton of Shorts or Bran or Chop Feed contains not much more than 180 pounds of digestible protein; while a ton of COULSON'S EGG FOOD contains over 300 pounds of digestible protein.

Now as "protein" is one of the most valuable parts of the feed for making eggs, you can readily understand that you will get more results from one ton of COULSON'S EGG FOOD than you would from a ton and a half of either shorts, Bran or Chop Feed.

Therefore, it would actually be cheaper for you and prove more profitable for you if you should feed your pullets and laying hens COULSON'S EGG FOOD every day.

Unless a food, however rich in protein, is relished, it loses much of its value.

Therefore, we make COULSON'S EGG FOOD in a condition that fowls will relish it.

They eat it greedily—THEY JUST GO FOR IT—because it tastes good to them and they like it so.

If you should feed only grain and a mash composed only of Shorts, Middlings and Chop Feed, etc., without any extras, in the way of animal foods, your average profit on your entire flock would probably not average over 75c per hen, per year.

If you should mix Beef Scraps, Meat Meal or Meat, etc., with the other feed, the profit might be increased to $1.00 per hen per year. If you should feed the hens COULSON'S EGG FOOD every day, a food that is just right, the hens will earn you a profit averaging from $1.25 to $1.50 per hen, and sometimes more, per year.

Now, if the above is true, and it undoubtedly is, one would do BETTER BY USING COULSON'S EGG FOOD, and save a lot of worry and both of mixing feed, etc.

(1¾) Tons of Shorts at $25.00 per ton would cost $44.00.
(1¾) Tons of Bran at $24.00 per ton would cost $42.00.

Therefore one ton of EGG FOOD is equal to $44.00 worth of shorts; it is equal to $42.00 worth of Bran, or $45.00 worth of Chop Feed or $50.00 worth of Corn; and it is better because it also keeps the fowls in more active and healthy condition.

COMMENTS:

184 EGGS PER HEN

Henry Graff, a prominent poultryman near Petaluma made a flock of 1400 hens average 184 eggs apiece during the past year.

THAT'S GOING SOME

Considering the large number of hens,—as there are always some hens that are not layers.

They were fed once every day on COULSON'S EGG FOOD.

I have fed your Egg Food for the past three months to my flock of 200 pure-bred Brown Leghorns with the best results. I believe it HELPS THE FERTILITY OF THE EGGS, as I have had a higher percentage of hatches than heretofore, and can cheerfully recommend to all poultrymen.
W. E. MERCER, Ventura, Cal.

This is the first season I have used COULSON'S EGG FOOD and I consider it excellent for the purpose. Since August last I have had MORE THAN DOUBLE THE NUMBER OF EGGS I ever had before from the same number of hens. A. A. HENRY, Rumsey.

I have fed your Egg Food and had good results.
S. M. BUTLER, (Arrowhead Strain B. P. Rocks.)

I find your Egg Food proves to be just what you recommend it to be.
E. M. SHELFORD, Cloverdale, California.

Have been using your feed since last August, 1904, and have never had such a healthy, happy lot of hens before. It carried them safely through the molt without any sickness and they are laying well at present with eggs at 35 cents a dozen.
MRS. E. M. HICKS.

Full particulars of your dealer. If he does not keep COULSON'S FOODS, etc., give us his name and we will tell you where and how to get them, and save you money.

A Sack of Coulson's Egg Food

The World Renowned
COULSON'S EGG FOOD

A Balanced Ration or Mixed Feed for Pullets and Laying Hens

Intelligent Feeding.

Feed the hens Coulson's Balanced Ration Egg Food. You can buy it nearly as cheap as wheat, and it will make the hens lay better than any other food.

A hen is simply an egg-making machine. Feed her properly and she is bound to lay eggs regularly. Feed as a mash one meal a day. Simply wet it up with a little water or skim milk, and it's ready to feed: it saves you time; it's the busy man's friend. Feeding a properly balanced ration the year round will yield double the profits if you feed COULSON'S.

Take the sack of Coulson's Egg Food, dump some of it out in a box—pour some water or skim milk on it. Stir it up so as to make a dry mash, (meaning not too wet), then pour it into the feed troughs for the growing pullets and laying hens. They should be fed COULSON'S one meal every day.

The supreme test of a hen is her Egg-Making Capacity. A good hen should lay about 200 eggs per year, which she will do if fed regularly on COULSON'S EGG FOOD.

Cut out this slip. A handsome needle case free.

Growing the Raisin Crape Commercially

By Robert Boot

The raisin grape, although introduced into this State more than fifty years ago, has not been of commercial importance more than half that length of time; the total production for the State in 1876 being in the neighborhood of 600,000 pounds weight of raisins, which increased by leaps and bounds up to 1894, when the production reached 103,000,000 pounds, at which time the industry was suffering great depression in consequence of unorganized producers' eagerness to force a twelve months' supply of raisins on the market in 90 days. The business of the vineyardist became unprofitable, raisins were sold for less than the cost of production, and many thousands of acres of vineyards were destroyed. This depression existed more or less acutely up to 1898, when the vineyard men organied under the name of the California Raisin Growers' Association, since which time the business has been carried on generally on a profitable basis.

The vines from which this large amount of product is derived are among the choicer varieties of Vinifera, imported from Spain, and are known as the "Muscat of Alexandria' and the "Gordo Blanco Muscatel," which is distinguished from the Muscat by its lower horizontal growth and its round berries, in contrast with the upright growth and oblong berries of the Muscat of Alexandria. The Malaga grape is also largely cured for raisins but it is destitute of the Muscat flavor and, being a thicker skinned, coarser grape, is not so highly prized for this purpose as the Muscat. This reason, and also the difficulty of removing the cap stem, make it objectionable as a seeding raisin, but, on the other hand, make it more valuable as a shipping grape for table purposes, and large quantities are annually shipped for this demand. It is said also to make an excellent quality of Valencia raisins for cooking purposes.

* * *

Our raisin production also includes the cured product of the Seedless Sultana and the Thompson Seedless, which amounts to to several thousands of tons annually.

The acreage devoted to these varieties of grapes in the State is estimated to be 64,000 acres, but this is probably an under estimate today, in consideration of the many vineyards planted in the last few years, which more than counteracts the loss by old vineyards being put out of commission and other causes. The average yield, per acre, covering a series of years, does not exceed 3-4 of a ton per acre for the State, proving that a considerable area is devoted to raisin grape growing that is unsuitable for its cultivation and unprofitable for the owner, as in most raisin districts there are raisin vineyards which are known to produce double, or more than double, that amount.

The counties of Yolo and Solano have the credit of producing and shipping the first consignment of raisins in merchantable quantities, closely followed by Riverside, San Bernardino, Orange and San Diego counties and lastly by the San Joaquin valley, which, from its favorable climatic conditions as to dryness of atmosphere and high temperature combined with abundance of water and suitable soil, has brought it to the front as the banner raisin district of the State, and in which raisins of the best quality, and largest yield, at the minimum cost of production, can be obtained by the vineyardist, with probably one exception in favor of Yolo county, where they turn out an excellent quality of Seedless Sultanas.

The future of the raisin grape and the raisin industry, as in all others, will come only as a reward for eternal vigilance. The Muscat vine, being one of the choicest and most delicate of the Vinifera family, is liable to suffer first, from any adverse influence, and there are many adverse influences waiting to prey upon it. The deadly, mysterious disease that swept the vines from the rich district of Anaheim and other southern districts and is now preying upon the vineyards of the Sacramento valley, is probably most to be dreaded, and no known specific has yet been discovered for prevention or cure. The minor evils of mildew oidium, and kindred fungus growths, are apt to attack the Muscat in preference to other and hardier varieties.

Then, in the insect world we have, first, the phylloxera which is already with us, but conditions do not seem favorable for its propagation at a very rapid rate, and it is principally confined to the heavy red loams; it is probable that this evil can be taken care of by being prepared with resistant stocks to replace its ravages, without diminution of our annual crop of raisins; then, the lesser pests of cut worms, sphinx worms, grasshoppers and the thrip, which is always more or less with us and can be easily controlled by early cultivation. I have never known injury from this cause where the cultivation destroyed all weed growth in a vineyard one week before the vines came out in leaf. Prevention is better than cure, and on general principles, a vineyard that is kept in high condition by careful and thorough cultivation and judicious fertilizing will resist many evils from which a neglected vineyard will suffer. The use of sulphur should not be forgotten; two or three dressings in the spring act as a stimulant to the vine, prevent oidium, and, I believe assists the early ripening of the crop.

At Work in a Vineyard.

Before leaving the subject of the welfare of the vine, a few words on the subject of pruning, which is a very necessary part of the important work of a vineyardist: Some vineyards boast of the fact that they have let their pruning by contract at so much per acre—say, one and a half dollars, including burning the brush, and then turn the contractor and his men loose in the vineyard with little, if any, supervision, with the result that when they get through, a first-class butchery has been accomplished. In some vineyards the brush is chopped off at equal length from the stump without regard as to the number of eyes left, no discrimination as to thinning, suckers even are pruned and left as desirable bearing spurs. Then again, others prune the stump bare as though the object was to grow suckers entirely, and after a few years of this treatment they have nothing but suckers, with the crown of the vine rotten and dead.

Whatever form of vine is desired, it should be remembered that the best bearing spurs grow from two-year-old wood and that this two-year-old wood should be growing on or around the crown at regular intervals to give the most space for the hanging bunches, at the same time by a free circulation of sap keeping the whole vine in a healthy growing condition.

Drainage, in some districts, is a question of vital importance to the welfare of the vineyardist, a water-logged vineyard with only a foot or two of soil available as feeding ground for

(Continued on Page 427)

BY J. W. MILLS, POMONA, CAL.

ADAPTION OF SOIL AND CLIMATE.

The disregard for the adaption of soil and climate in the growing of fruits is no douht responsihle for more loss to the grower than the ravages of insects and plant diseases comhined. A certain variety of fruit is planted and when it first comes into bearing good results are ohtained and immediately a lot of growers plant the same thing, only to find that the variety does not maintain its first vigor or productiveness. Its first success was either due to its vigor of youth or a chance succession of favorable seasons. Trees that fail to produce favorable crops after they get to be five or six years old are a worse pest than scale bugs or rust. They lead us on a will-o-the-wisp chase year after year, using up our time and money, to say nothing of our patience and opportunities. Olives were planted by the wholesale in Southern California hefore the profit side was worked out, just because the old mission trees grew well and bore some fruit Incidentally, Northern California caught the tag end of the olive boom as it does all the rest of the booms and has found that it can grow olives at a profit hecause the climatic conditions are favorable. Southern California has not grown them at a profit because the climatic conditions are not favorable. Had the Washington naval orange not fitted into the soil and climatic conditions as perfectly as it does, no amount of coddling or cultural persuasion would have enabled us to turn out over 25,000 carloads of oranges per year. Even here, two hours ride will separate sections which produce two distinct qualities of Navel oranges no matter how favorable the season may be, while in those sections which produce the finest, as a whole there are large areas which will seldom produce good fruit, due entirely to local climatic conditions.

* * *

The experiment station situated near Pomona has, or has had growing from 150 to 200 varieties of plums that have proven to be valuable in some section or other, either in this or some foreign country, but here, not over 15 or 20 are worth considering. Another striking instance is the behavior of some of the Persian grapes, which absolutely refused to bear at all in the Pomona valley, but produce enormous crops when grown in the Coachella valley. There could be hundreds of examples cited that would only emphasize these facts. It is very plain that a more widely scattered series of experiments carried on by the State would result in much more good than one station centrally located, even with the difficulties that arise from only partial control with co-operative experiments. This is the new policy of our Agricultural Department of the State university.

The marketing of "pig feed" ruins the market for better fruit.

LATE PEACHES FOR SOUTHERN CALIFORNIA.

Editor Cultivator: Will you kindly tell me what kinds of peaches I ought to plant for a late crop, both cling and freestone and about what time does each ripen and what is the color of each. We are looking for some that will he reasonahly sure to bear each year in this locality.

How about the Henrietta as a regular hearer and how does Orange Cling and also Lemon Cling bear in comparison?—Chaparral, Riverside.

Henrietta is the best late yellow cling we have. It is a sure hearer, equal to the Salway, which of course is a freestone. During the past 10 years there has not heen a failure of these varieties with us. The latter is a large yellow freestone that is ripe up to the 25th of Octoher. There are several varieties of peaches that ripen later than the Salway but they are shy hearers and not up to the standard. We are sure that they will not he profitable. Salway is pre-eminently the late peach for Southern California. It is large even when the trees are overloaded, of fine quality and a prodigious bearer.

Henrietta is not a desirable peach for table use except when canned. It is a good hearer and of fine quality and holds its load without propping as the tree is an upright grower, so much so that it requires pruning to spread it.

Orange Cling is not a sure hearer and produces a poor grade of fruit compared with the same grown in the northern part of the state. The Lemon Cling is a dead failure with us, it bears fairly well hut it is impossible to get marketable sizes. Canners will not take it and it is not fit for any purpose hut canning.

Dr. Pilkinton is a very nice white freestone that is just beginning to ripen now, the 1st of Novemher, hut we have failed to get more than five or six pounds from a tree in one season. The hirds always save us the work of picking the fruit. Our advice now is to stick to Henrietta and Salway and not try any other late varieties except in an experimental way.

* * *

OCTOBER PEACHES.

Editor Cultivator: I am looking for some information about peaches I want to raise some for grocery trade in Octoher. I have a few Salways but I want something later too.

I want to thank you for the information you give me each week.—R. H. B.

We can't do better than refer you to our answer to Chaparral of Riverside. The latest peach we have, Dr. Pilkinton, would hardly be satisfactory as it is a shy bearer. You would have to plant at least an acre in order to get so small an amount as 600 pounds.

Southern California has not proven to be a peach country. The trees don't act right and they do not turn out the fruit. There are a few varieties that are the exception, but we cannot count on recommendations that are based on experiments or records made in other sections.

WOOLY APHIS.

Editor Cultivator:—I enclose a twig from one of my apple trees. Will you please he kind enough to let me know what is on it and if it will harm the tree and if so what can I do to get rid of it? Yours truly, J. I., Upland.

Your tree is infested with wooly aphis. It is easy to kill the form above ground, hut you should look for the root form, which is by far the most destructive. Almost any spray will kill those in the tops—distillate is hest. For root form: Dig down six inches and make a basin three or four feet around tree, just before rains come. Distribute in this basin ahout three pounds of tohacco dust. The rains will carry this down and kill the aphis.

DYING ORCHARD.

Editor Cultivator:—I have in my orchard a spot of ground where some large live oak trees were dug out. The fruit trees did well for five or six years and then they began to die, one or two each year, and the circle is still increasing. Can you tell me the cause and what will stop it from spreading? Please answer through the Cultivator. —J. H. S., San Jose.

This matter of decaying oak roots killing other trees planted on the same ground is a very common one. Out in the San Gabriel Valley near Los Angeles, these roots have doubtless caused more "root rot" than all other causes combined. We have examined several cases, where the tree first looks sickly—leaves become spotted, off color, and small. Upon digging down, the old oak roots were found in a soapy mass. The trees had been planted for nearly ten years. This condition of affairs was found in the case of every sick orange and walnut tree examined. Live roots do not so affect the orchard trees. We know of no remedy except to take the old roots out.

BEEKEEPING FOR WOMEN.

Mrs. J. B. Ames.

Actual experience has proved beekeeping to be a profitable as well as a healthful occupation for women in California. The ready market for comb and extracted honey removes all difficulties in disposing of the product of the busiest of all animals and the mild climate permits the outdoor work necessary for the care of the bees during a long and pleasant season.

The woman who would keep bees, either to supply her household needs or with a view to earning a living, has but to understand and apply the two following very simple essentials to the profitable raising of bees. They are, first: that the animal life be properly nourished, and second: that Nature be so assisted by intelligent methods of keeping and reasonable care as to give best results to the keeper. But these essentials may be supplied here in California with a minimum expenditure of work and money. So many localities furnish abundant food for the bees that the question of feeding them is solved for the keeper, while by an intelligent selection of location and methods of handling the best results are easily obtained.

There being no winter problem in California, it is not necessary to carry the bees with six months' supplies into the cellar. In colder climes the bees are "wintered" in cellars, where from Thanksgiving until the middle of April the hives are stored in cellars for protection, in spite of which, however, winter loss is common. A beekeeper in Wisconsin writes: "On April 12th I took out the last bees. From then till the 22nd we had heavy frost and cold weather. On the 26th and 27th the weather is so unfavorable that one day they work and the next day they have to lay up again on account of high winds and cold." We in California have but to read this from an Eastern beekeeper to appreciate the advantages of California's wonderful climate for beekeeping. In fact, it has been the writer's experience that the bees not only stay on the same stands but also gather nectar every month in the year, so that in early spring they are in good condition to work and increase. All the work attendant upon the keeping of bees can thus be readily done by women and the prevailing wholesale price of ten cents per pound for comb and five cents for extracted honey yield a handsome profit to the industrious keeper.

That there is room and that there are abundant opportunities for engaging in beekeeping in California is shown by the present problem of disposing of the annual increase. And why should not women take up this industry since it is so pleasant and profitable an occupation for women? At present it is largely confined to farmers' wives and daughters, who already have many duties to perform, but the pleasant nature of the work bids fair to attract women who will be able to devote their attention and energies to developing the industry on a larger scale.

It is a well known fact that honey bees will select a home in a hollow tree and there not only attend to all their natural wants and provide for an increase, but also lay up a surplus store of honey. Climatic conditions in California are so favorable that it only remains for man to turn them to his benefit. Here there is no expense for feed for the bees feed themselves the year round. They not only feed themselves, but also feed and care for their young, thus relieving the keeper of much care so that there is no need to interfere with the increase except at the swarming season, then to provide new homes for the new swarms, where they can thrive and work and produce that delicious food the value of which I trust will some day be fully realized by rich and poor alike.

Although California's output of honey in 1905 will be the largest in many years, it will be quite insufficient to supply the extraordinary demand caused by the short crop in other States. One State usually leading in honey production will produce hardly a fourth of a crop this year while another is nearer to a honey failure than it has been for twenty years. Here is woman's opportunity in California to enter this profitable business, which has also always been to the writer a pleasant one.

HONEY AS AN ARTICLE OF FOOD.

Nine out of every ten people either think of honey only as a luxury, or look upon it with distrust, thinking that most of the honey on the market must be adulterated. If the people in general knew how much honey is produced, how economical and how much healthier it is than the many kinds of so-called table syrups manufactured, there would be such a demand for this most delicious product of nature, that the honey market would get firmer, There would be more demand, and consequently the bee industry would grow until we could justly be proud of what can be done in this line in this state. What has brought about such a condition and how to restore the confidence of the people to the most healthy, economical and toothsome sweetening known, is an important question. One of the causes of this condition is that very few people know and can get any reliable information as to what is being done in many small out of the way places in this and other States. It is impossible to get anywhere near the figures showing the number of colonies of bees and the amount of honey produced.

All honey shipped from this State is pure, and it is safe to say 99 per cent of the honey sold in the State is pure if it is produced here and sold for honey. A beekeeper would not mix adulterants in honey because it is decidedly to his interest never to sell anything but pure honey in the local market and retailers and commission houses could not adulterate it at a profit. Another cause of distrust by the public and depression in the honey market is the widespread publication of erroneous and untruthful statements about the adulteration of honey in many periodicals.

LIME ON ORCHARD SOILS.

There are numerous orchards that have made a good growth of trees and yet have never borne good crops. This is generally due to some deficiency of fertility in the soil. Frequently this deficiency is the nitrogen content, and the nitrogen content is low because the soil is acidy, which condition prevents the growth of leguminous crops. Nature's way of putting nitrogen into the soil has been by the use of large numbers of varieties of plants bearing pods, all of which have the power of taking the free nitrogen of the air and fixing it in soluble form in the soil. The instruments for this transformation have been plants of a fungous nature known generally as bacteria. These cannot exist in a soil which has too much acid, but acid can be easily neutralized by an application of lime, either in a caustic form, which is the burnt lime of commerce, or in a slowly soluble form, which we get in ground lime rock.

APIARY NOTES.

An expert in the United States Department of Agriculture estimates that the flora of the United States is capable of supporting ten times the number of colonies of bees it now supports.

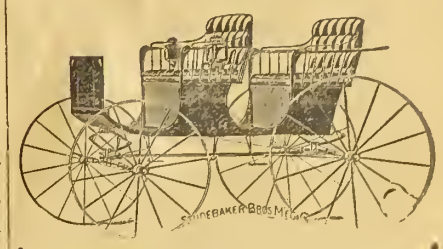
Mr. Frank Benton, in charge of the apiarian work of the division of entomology of the Department of Agriculture, estimates that the value of apiarian products annually amounts to $20,000,000.

A French writer says that beekeepers generally live to be old, but this longevity is not accounted for solely by the use of honey, but by the inoculation of bee poison, either by breathing it or being stung.

A pair of pruning shears can be used every month in the year.

Remove the wormy and perforated fruit from the trees.

Studebaker Vehicles



Stand Without an Equal

They are constructed throughout of the best material, by skilled workmen in the largest vehicle factory in the world. The wise buggy or wagon buyer will always purchase a

Beautiful and Productive

A Section Where Soil, Climate and Water Combine to Produce Prosperous Cardena

For the first time in a year we recently visited the productive section about Gardena and there was such a record of growth and improvement that even for California, it caused much surprise. Gardena has never claimed to be a tourist resort. It has no tourist hotel and has not become a residence section for exceptionally wealthy people, and for this reason it cannot be said to be one of the "show places" of Los Angeles County. But to the man from Missouri, it has the capacity of "showing" the true wealth of productive soil with abundance of water in this wonderful climate. Therefore there have quietly sprung up a vast number of cottage homes surrounded by small fruits, gardens and poultry houses. The holdings have been small, that is two, three, five or usually not over ten acres. This has led to extensive culture and to the securing from the soil, its greatest returns. Only occasionally the Chinese and Japanese gardener is seen. This is largely because of the Americans grasping the opportunity and occupying the land before the Asiatics secured their foothold. In other words the "Dutch have taken Holland."

The first question that comes to mind in seeing the vast quantity of products from this section, is, where is the water secured for producing them. It is quickly answered by the puff of the gas engine which is heard in any direction one may turn. One plant which we were shown, which was installed at a comparatively small expense, was raising in excess of one hundred inches of water at the time it was shown to us. This is made possible by the great quantity which is found in a deep bed of water bearing gravel only about one hundred and fifty to one hundred and ninety feet from the surface. This vein of water bearing gravel has been found to contain an almost inexhaustible quantity of water which always rises to within fifteen or twenty feet of the surface in some cases flowing in winter. Some of the ranches are supplied by a plant, operated in the interest of all who are members of a co-operative association. Other ranches have their own pumping plants and are entirely independent of the others. Within certain districts, which cover nearly the entire section of Gardena, Moneta and Strawberry Park, water may be found with certainty. All told there are about ninety wells in the community.

When we speak of Gardena we also include Strawberry Park and Moneta which are really a part of the section. The Strawberry Park people already begin to feel their importance and claim a little community all of their own, which seems to be justified by appearances on the line of the two electric roads which pass through this rich section. At Strawberry Park is erected a little station where the piles of berry crates as big as a small house were in evidence showing the magnitude of the small fruit business of that community and the wisdom in selecting the name for that vicinity.

Moneta is the older section of the three. Its main street is a continuance of Western avenue of the city of Los Angeles and is directly south of Hollywood. The village has several small stores and shops. Of the many products, of course small fruits are the greater factor, though the building of the Gardena-Moneta Co-operative Association midway between Gardena and Moneta, shows that dairying is a most important factor in the advancement of the community's interest. About Moneta the soil is very rich and an abundant producer when properly planted. In asking various of the producers as to the products best adapted to the section not only were the products of the dairy, of poultry, and of berry-fields stated as the producers of wealth but the possibility of onion culture and other garden products given first place. Onions have been grown in no great quantity but from the quality of the soil and the conditions which prevail, there can be no question as to the adaptability of that product.

* * *

Regarding the Gardena-Moneta Co-operative Association we may say that it has a membership of forty-two, shipping daily to Los Angeles retail market about 3,000 pounds of milk and the cream from about 2,000 pounds of milk. Last month a check received by the association for its products, amounted to $1,266. This association has been very satisfactory to its members and now owns a small strip of land on which the building is erected, all of which is the property of the members. It not only co-operates in marketing products of its members but in buying feeds and other merchandise as well, thus securing wholesale prices.

The berry growers are not so well organized as the dairy men but their efforts have given returns exceptionally satisfactory. One berry grower in Strawberry Park who has specialized on Cuthbert raspberries, refuses to give the exact returns for the past year, from his little quarter acre patch because as he said, it would be taken for a California story and he would not be given credit for telling the truth. The soil about Strawberry Park seems to be particularly adapted to raspberry culture, it being a rich, sandy loam and a soil which is most readily worked. This grower said that he had much better results from the Cuthbert's than from the New Rochelle or the black caps.

Mr. West, formerly a large grower of strawberries and a pioneer of the place told us that from a ten acre patch he marketed the second year over 140,000 boxes of berries which commanded from five to twelve cents. At present Mr. West finds alfalfa a very satisfactory crop.

Another advantage which is claimed for this section is the exceptional facilities for shipping the products into Los Angeles. The rate of ten cents per hundred pounds is secured and there is the advantage of two electric lines to carry the fruit. The shipping of berries occurs in practically every day in the year, though the busier part of the year is from March to September. Some idea of the magnitude of the business may be had from the fact that the daily shipment during the season is between three and four cars. Besides that there are other large quantities of vegetable and dairy products.

* * *

While not of important agricultural interest, yet of the greatest interest to the family of the agriculturist, we may mention that the conditions for moral and intellectual development are not least which can be said of this section. In Gardena there are two churches, Methodist and Baptist, at Moneta there are two churches, the Methodist and Presbyterian. In schools each of these districts including the Strawberry Park section has its grammar school while the three unite in a union high school which is at present held in the second floor of the Gardena grammar school building. Steps have been taken looking toward the construction of a creditable high school building embracing the three districts but as yet this is in the future. Another factor in the progress of the community, especially its agricultural progress, is a live, up-to-date Farmers' Club. C. W. Stephenson, its president, injects his energy into it to the end that its meetings are not only a pleasure socially but a benefit intellectually.

All told a home seeker will find no better section where a pleasant home may be made amongst a pleasant and thrifty people, where the soil responds quickly to intelligent culture and where a climate the equal of any in matchless California, than at Gardena, home of a happy people.

CITRUS FRUITS

By C. A. Day. Pasadena

LEMON NOTES.

The Outlook For California Lemons.—There are different theories held by various expert lemon growers, as to varieties, methods of pruning, culture, irrigation, fertilization, forcing into bloom at the right time to secure summer lemons, curing and marketing. It may, with truth, be said that the lemon industry of Southern California has in the last few years, and is still, in the stage of development. Experiments and experience are teaching the lemon grower as to proper methods of culture and handling and the lemon industry of California is rapidly developing into a permanent and paying business.

The California lemon grower has in the past been in a measure handicapped by inexperience and competition of foreign lemons, which had an established reputation in our eastern markets, but with improvement in our methods of culture and handling, the California lemon is winning a reputation and standing in the markets of our country. In the case of all farm products there are periods of over supply and temporary depression of prices and lemon growing in California has had its share of these. But with an established reputation in the market and a reduction of the lemon acreage from the budding of lemons to oranges, the outlook at the present time is very good.

One of the mistakes made in the past has been in the planting of lemons in locations totally unfit for successful lemon growing. Lemons require a nearly frostless location in order to produce lemons for the summer market, the only market that gives paying returns. Many of the lemon orchards that were planted in locations unfit for lemon culture have been taken out and budded to oranges.

In some sections a very much better quality of lemons are grown than in others, probably due to the quality of the soil. The process of weeding out the poorer quality of lemons and the survival of the fittest will result in the raising of the general average in the quality of California lemons.

The lemons of the Semi-Tropic District Exchange have during the year past, given the highest average net return, $833.71 per car of any district exchange of Southern California.

Mr. Leffingwell's lemons have made net returns during the summer of from $1000 to $2400 per car, the latter price the highest for any car of lemons sold by the Semi-Tropic Exchange.

The writer heard Mr. Leffingwell remark that his average yield would be one car of lemons per acre. We have in this case an instance of a lemon grower with 125 acres, who has by correct methods of culture and handling, succeeded in producing a uniform pack of fine quality and won and established an enviable reputation for his lemons in the eastern markets.

* * *

Fumigation as a Stimulus to Produce Fall Blooming Lemons.—Mr. Volney Craig of Lamanda, with 60 acres of lemons holds to the theory that fumigation is a stimulus to the lemon tree and results in free blooming in the fall. It is a well known fact that for a summer crop of lemons we must get the trees in full bloom in the fall of the year. When questioned as to his experience, Mr. Craig stated that he fumigated in the years of 1900,1901, 1904 and secured good crops of summer lemons.. The fumigation for 1905 has been followed by free blooming of the trees.

Mr. Craig's plan has been to fertilize with blood fertilizer 30 days preceeding the fumigation and follow the fumigation with a thorough fumigation in basins, thoroughly wetting the whole surface, the irrigation for the rest of the year in furrows between the rows. Whatever effect the cyanide may have in stimulating the forces of the tree, this we do know, that it destroys the crop of scales and fungi, and opens the pores, which would in this case have the effect of a stimulus to the tree, this in connection with the stimulating and forcing effect of the fertilizer and heavy irrigation would tend to bring out the bloom immediately after. In referring back to the years in which fumigation apparently produced a good effect upon Mr. Craig's orchard, in the years 1902 and 1903, the orchard was not fumigated and the crops of lemons in those years were light. As the Craig ranch has its own water plant the supply is always ample and there is no stinting at any time in the amount of water supplied to the trees. Some of our lemon groves practice pruning early in the fall as a means to force the trees into bloom. With proper culture marketable sized lemons will be produced from 8 to 12 months from time of blossoming. The lemons in the interior of the tree maturing first and those near the end of the branches last. The application of fertilizer early in the fall is important and along the line of applying nitrate of soda to orange trees just before the blossoming season.

Lemon trees should not be forced into bloom too late in the fall, the very small lemons are susceptible to injury from frost which usually comes in the last of December and in January.

* * *

The first quality of lemons are those which come to merchantable size while yet green. The culture, fertilizing and irrigation should be such as to bring the lemons to this size before they begin to change color. The forcing process should be constant and even, in order not to produce coarse, inferior fruit.

* * *

Pruning Lemon Trees.—In practice, there are several systems of pruning the lemon, but all agree that it should be headed low with broad open top. The low head facilitates the picking from the ground, the breadth of top gives space for a large yield of fruit and the open top gives fruit in the interior of the tree. The latter is an important feature, as the fruit in the interior of the tree matures first and with fall bloom will be ready for the early summer market.

* * *

When to Prune.—With young trees some growers prune three times in the year, the object being to grow the desired head without unnecessary waste of the vitality of the tree in growing superflous wood. With old bearing trees, some growers prune throughout the year, removing from time to time the surplus sucker wood and diverting the vitality of the tree to the fruiting wood. There is a class of growers who make a practice of pruning once a year and then have to remove a large quantity of upright sucker growth. To my mind this seems a useless waste of the vital forces of the tree, to allow this wood to grow the entire year.

Different varieties of lemons have different habits of growth and the pruning should be governed accordingly.

SAVING THE WASTES.

The Cultivator has very often made a point to the effect that greater efforts should be made toward saving the wastes of the farm, especially of the fruit orchards of the State. It has always been found true that the market had plenty of room at most remunerative prices for high grade fruits particularly, but, that often the price of the best grade of fruit is affected by the vast quantity of inferior or indifferent stuff which is offered. Yet rather than see such fruit go to the dump, an absolute loss, the average farmer will pack it as best he can, pay freight on it to market and run the chances of securing costs and a little for himself besides. To overcome this system of handling indifferent fruits, various factories and canneries have been established to handle such products. For marmalades of citrus fruits, factories for processing candied peel and the manufacture of citric acid have been established. There are at Riverside and at Redlands good sized works where marmalades and candied peel are manufactured. But of course in comparison to the vast quantity of cull fruits of the State these are merely a drop in the bucket.

Now another factor is in the field which will be enabled to handle greater quantities than those which have heretofore made the effort to handle these goods. This is not only because of the fact that the works are larger also from the fact of the putting up of a cheaper product which will command vastly greater consumption than any heretofore outlined plan. The idea is not to put up a fancy high priced article so much as to concentrate various fruits for use and economical transportation and in such form as to be of value to bakers, confectioners and even for use in the commissary department of the army.

The process by which this is done has been studied out and introduced by the Sherman Cancentrated Fruit Co., of San Francisco, and now the company has a branch in Los Angeles which is in a large part owned by Mrs. Delia R. Rawson, who is its manager. Mrs. Rawson recently showed the writer various products manufactured by these processes, one of which is the highly concentrated juice of the lemon, a little of which on the point of a spoon stirred in a glass of hot water made a glass of very choice flavor and as refreshing as the fresh juice of the lemon. Another product was orange flour which might be prepared for the breakfast table and eaten as a fruit or used in making pastries, cake and various other baker's uses. Still another grade, especially of oranges, where the fruit pulp is reduced in the vacuum pan until it becomes the constituency of leather. This is taken and used as mentioned above for fillers for pies, and cakes but does not make an attractive appearing dish for serving at the table.

This process is especially valuable in taking up waste berries from the market, plums, prunes, apples, in fact any fruit and many of the vegetables which are found in the market. One product which we tasted, which was most delicious to eat directly from the hand was the reduced pulp of raspberries from which all the seeds had been removed. This product was sweetened and was equal to a confection. This and many like products are valuable for sauces, syrups for soda fountains as well as pies.

The United States Department of Agriculture has made a careful examination of some of these products and reports that this solidified fruit is distinctly compact, non-elastic, comparatively impervious to atmospheric moisture, yet quickly dissolvable, digestible, free from fiber and retaining the natural flavor of the fruit, though it has lost entirely the original form of the fruit; in contrast with the dried fruit, which is spongy, elastic, quickly absorbant, yet not dissolvable, except after long soaking, accompanied by mechanical agitation, retaning the original fiber of the raw fruit and requiring cooking before being suitable for food.

The new product is entirely distinct from "dried fruit" as understood in trade and commerce in this industry, and no comparison between the two could arise.

In comparison with fruit paste, this produce differs in that it does not necessarily contain the added sugar, to insure it against decay and deterioration, the addition of sugar being to suit the taste of the consumer. It contains the natural flavor of the fruit and is dissolvable into either fruit pulp or juice by the simple addition of water, whereas fruit pastes have undergone chemical changes in the process of manufacture which render their restoration to their original pulp or juice impossible.

Mrs. Rawson showed us many letters commending the product from bakers and other consumers.

We wish the Sherman Concentrated Fruit Co. success and hope the growers will find in it a profitable means of waste disposal.

VALENCIA LATE ORANGE TREES

Are scarce. We will have about 75,000 citrus trees, nearly all 2 years from bud and mostly Valencias, and we are offering them cheap. Give us your order now before they are culled over. Also have some Marsh's Seedless Grape Fruit, Dancy Tangerines, Navelencias, etc. We can furnish these from our Glendora nursery, or other nurseries. Address

RAISING PLANTS FROM DATE SEEDS.

It doesn't take such a long time to raise plants from date seeds as some seem to think. Examine the flat side of a date seed. In the middle you will find a small round hole. File over this carefully until the white germ shows, and then plant it and keep it very moist. The warmer the place you set the pot in the better. Fresh seed will sprout in ten days or two weeks

KEEPING CANNA BULBS.

I would say to those who have trouble in keeping canna bulbs that the secret is never to place them with the tops up, after you have cut them off. After digging them up, spread them out on the floor until the dirt is dry on them (keeping the roots turned upward all the time). When dry, pack them in a box with dry sand or soil, cover and set away until spring. In Winter, after the first hard frost, our cannas never look well and seldom make good growth until April, so that during winter the ground may as well be taken up with some other plants, and the canna clumps held for planting until April.

FREESIAS.

When the gardens are redolent with the sweet, apricot-like fragrance of Freesias, is the proper time to mark and secure the flowers from which bulbs or seeds are wanted in the future. There are two varieties in cultivation—one and by far the most desirable, is milk white, the other a rather dull shade of pale yellow. Intermediate between these are variously striped, spotted and mottled hybrids, and so freely do the two species hybridize and sport, that it has become practically impossible to procure seed whose purity is to be depended on, unless the grower is certain that there are no intermediate forms in the immediate vicinity.

For this reason, if the pure white form is desired, it behooves the future planter to make the selection when the bulbs are blooming and to make critical inspection of neighboring gardens as well, otherwise he is without assurance that his seedlings will not turn out contaminated by the busy bee.

Some growers of considerable experience hold to the fallacious idea that the bulbs in time change their character, and that such as originally produced pure white flowers after three or four years, if undisturbed, become largely converted to yellow. There is no reason to doubt that this metamorphosis has been effected by the chance cross fertilization of a single flower by a bee or some other insect, and from the resulting seed springs bulbs of such vigor, that in a few years they can quite repress and supplant the original stock.

There are no exotic bulbs in cultivation in California not excepting a calla that is more tolerant of abuse than a Freesia. A Freesia never dies unless crowded out of existence, or unless disease enters the bed. Ordinary maltreatment is more than congenial to them. Dropped in a gravel walk they will spring up and flourish fairly well, cheerfully unmindful of such small episodes as being walked upon while in leaf. They are of course responsive to generous treatment and with an annual top dressing—make returns in size and abundance of bloom.

OLD FASHIONED FLOWERS.

Gardens of old fashioned flowers appeal to everyone as they mean the same sentiment to all of us. The varieties of flowers comprised in these gardens are such that anyone can grow them, just as our grandmothers did. If you have never tried one, by all means decide to have one next year.

Wash the soil from the roots of roses that have become "potbound" and repot in fresh soil.

FLOWERS IN THE HOUSE.

The old notion still holds among many people of this and other lands, says the Family Doctor, that flowers are not wholesome in a sleeping room. Certain plants, among which are the geranium, the lily and the begonia, are supposed for some unexplained cause to give off an odor at night especially obnoxious, but scientific knowledge and numerous experiments have repeatedly disposed of these delusions. It is true there are a few tropical plants which give off a perfume unhealthful to breathe at any time, but these plants are rare.

The green leaves of all flowers are, on the other hand, most beneficial, since they purify the air. That doctors are beginning to recognize this is shown by the fact that a New York hospital has a flower ward, which is used for the treatment of suitable cases. Persons confined to their bedrooms with a bad cold, influenza, bronchitis or even consumption cannot do better than surround themselves with pots of any kind of plant that has a profusion of green leaves. Geraniums are the least valuable in this respect, and strong smelling flowers like musk, should be avoided.

How the leaves act as therapeutic agents is easily explanied. What renders the air of a room stuffy and unwholesome is the carbonic acid gas we breathe forth. Green leaves, however, breathe it in, consume the carbonic acid gas and breathe forth pure oxygen. Moreover, they give off in vapor the water taken up by the roots and thus act the part of a bronchitis kettle.

ENGLAND'S GARDEN CRAZE.

The garden craze of the last few years, for which we predicted a brief life, although a merry one, has become what its real votaries thought it would—a source of permanent interest.

This emphasis of enthusiasm has brought about the cult of the garden ornament, and those who are able to afford to do so, are searching far and wide for some piece of sculpture that shall harmonize with the style of the gardens, be they Elizabethan, Jacobean, or of the Georgian period.

Until one remembers the depredations of the Puritans during the civil wars in this country it is difficult to understand how it is that the Elizabethan and Jacobean periods did not produce a greater number of pieces of garden sculpture than they did. Most of the images of the Jacobean gardens the Puritans demolished, particularly if they were lead, a favorite metal in those days for the manufacture of such ornaments. Lead of every kind was precious for the formation of bullets.

Lead images are now highly prized for garden ornaments, and so are those made of terra cotta, and, of course, of marble and stone.

There were many quaint conceits in garden ornaments in the days of long ago that did not appeal alone to the beauty loving eye, but aroused the practical joker of the period. Any one who has visited the czar's summer palace of Peterhof, near St Petersburg, will remember in the garden at one of the small villas adjacent to the palace, trick fountains, as they are called, innocent looking marble seats, upon which no sooner has the visitor sought repose than he is drenched with a shower of water. Such trick arbors and trick seats were quite a feature of the gardens of long ago.—London Mail.

RURAL CONTENTMENT.

"Some way when I visit in a village or city, there comes over me a pent-up feeling. The sameness of it is tiresome, and I doubt if I could enjoy it as well as my country home with its broad, fertile acres. Back of the house we see the hills and woods, and I often think of the words, "'The strength of the hills is His also." I wonder if I should be as contented, should I ever leave the home where the happiest and best years of my life have been spent."

SECTION OF YEAR-OLD PLANT PHOTOGRAPHED IN THE FIELD

Buy Burbank's Rhubarb

This creation of California's plant wizard is practical for you in your garden. It's ever-bearing—(Winter, Summer, Fall and Spring.) Crimson flesh. Never stringy. Stalks small but juicy. Tender and luscious as a berry. Needs little sugar. Everything you've wanted rhubarb to be.

Roots **Northern Grown & Robust.** Three year's successful bearing in our trial grounds. Require but little water. Plant now and cut this season.

How to Cook the Rhubarb.—Since the Winter Crimson requires much less sugar than the ordinary varieties, a few suggestions as to how to cook it may be found useful. The color of the rhubarb before cooking is of a greenish crimson which, when cooked, turns into a rich, clear shade of crimson. Bake slowly in earthen dish, sprinkle lightly with sugar and just cover with water. For making jelly and preserves it is excellent, and its medicinal properties are fine.

Price prepaid, small roots 25c each, $2.50 dozen; larger roots 50c each, $5.00 dozen.

In the Vegetable Garden

ONION GROWING.

The first thing to determine is what sorts will sell best in the market, when to plant and how to cultivate them in order to have them ready for the market at the right time.

The next and most important things for those contemplating an onion crop is that their seeds be of the best and of the variety the commission men and consumers demand. As much depends upon the superior quality, care in selecting very rich, fertile soil must be used in preparing the planting beds, adobe and heavy loam being barred entirely.

From choice seed comes smooth, nice well shaped onions while from poor seeds you get all colors not true to name and classed by commission men as doubles, splits, scullions and rough tops all undesirable.

Another precaution to be borne in mind by new beginners is the acreage, as onions are a crop demanding much cultivation and one acre well cared for will net the grower better returns than five acres poorly tended.

As soon as the crop is ready for harvesting, it is necessary to have drying barns or sheds to cure them in, as direct contact with the sun will damage them so as to make them unfit for market.

Texas growers who had good barns to dry their onions in, this year made from $260 to $300 per acre, while others without drying barns failed to make expenses.

The most successful Texas growers plant their seeds in beds about two and a half or three feet wide, usually with a drill, making the rows about six inches apart. After the seed is drilled they cover the ground with straw or hay so as to protect the seed from the sun until after it germinates and to keep the ground moistened until after the transplanting season, when the onions should be about as large as a lead pencil. Then they make a bed wide enough to hold twelve rows about a foot apart by throwing up a border on each side.

Onions are planted about five inches apart in rows and just as soon as planted are flooded with water and as soon as the ground is dry enough they are cultivated with a hand cultivator. This is repeated about every seven or eight days. The ground must be kept moist and not allowed to bake, or the onions will be ill-shaped, which will make them of much less value.

To successfully grow onions and get desired results the land must be cultivated often and kept in the very best condition.

CRIMSON WINTER RHUBARB.

Mrs. T. B. Shepherd.

The most valuable acquisition to the horticultural world in many years is the new everbearing crimson winter rhubarb, tested, introduced and recommended by Luther Burbank. It promises to become the most profitable thing the soil produces. Its superiority in every way to the old deciduous rhubarb makes it by far the most desirable variety worth growing in California.

This new prodigy of the soil is everbearing, requires no stringing, has a mild acid taste combined with a delicious berry-like flavor, and when properly cooked its sauce is a most beautiful bright strawberry red. There is no fruit offered in the market which when stewed excels it, either in delicacy of flavor or in beauty. It is easily grown and comes into bearing the first year, paying all the expense of plants and cultivation, picking, packing, etc., and a handsome profit besides; while the following years the profit is enormous. From a little over three-quarters of an acre last year the writer gathered and shipped seven tons of stems from January 10th to July 10th, at which last date the plants were seventeen months old. We received 4½ to 5 cents per pound. A much better price could have been realized if we had sought a market outside the State where winter prevails during the height of this fruit's season.

This rhubarb is very easily grown. The roots instead of being chunky like the old variety are long like the parsnip and grow from 12 to 18 inches in length. Young plants about the size of a penholder set out even as late as July, if properly cultivated and cared for, will come into bearing by Christmas. The plant usually sends forth from six to ten crowns, but frequently make many more, and as fast as the stems are pulled others take their places. They are at their best from October till June.

Although the plant is everbearing, it is well to give it a rest during midsummer if a heavy crop is desired during the fall and winter. The stems can be used at all seasons, and the sauce, like that of the apple, possesses the great merit of being always welcome, having a peculiar flavor of which one never tires. It can be used as a standby at all seasons of the year. A fruit so highly appreciated in a country like California, where fruits are abundant at all seasons, must be hailed with delight in those regions where winter reigns many months in the year, and where the delicious products of California's sun-kissed orchards are hailed as welcome visitors.

Crimson winter rhubarb will grow in any good rich soil, and requires no fertilizer. It takes from 3,000 to 4,000 plants to the acre, and after becoming established requires water but three or four times during the dry season. To make a success of this plant financially it should be grown in such quantities that it can be shipped by the carload. There is not only the home market to be supplied, but the shipping market is always hungry and can be retlied upon as a regular outlet for an immense product. The cultivation of this new wealth-producer is an occupation in which any intelligent energetic woman can succeed, and I hope in the near future that women, realizing the handsome profits and healthful work connected with its cultivation will be leading in the industry and growing hundreds of acres of this rhubarb. I know of no product the ground can produce that will yield greater profit with less labor and in a shorter period than crimson winter rhubarb.

OUR CELERY—HISTORICAL.

The celery industry was first introduced in Orange county by the late D. E. Smeltzer, who came west about fourteen years ago in search of celery and winter vegetables for his commission house in Kansas City. After a few weeks spent in the vegetable districts about San Francisco, he came to Los Angeles, where E. A. Curtis aided him in securing some celery, of the old green top variety, to test its shipping qualities. The first shipment was a complete failure; but later in the season, by new methods of packing, they were able to ship the celery successfully.

During Mr. Smeltzer's stay in Los Angeles he learned of the peat lands of Orange county and after a visit for inspection as to its natural advantages and adaptability for celery growing, he secured a piece of this land.

Wild celery growing here to a height of six or eight feet was sufficient evidence of the soil's fitness for his purpose.

The first two years, however, were failures, for various reasons learned later. The third year proved more successful. A fair article was raised and several carloads shipped to Kansas City with satisfactory results. From that time until the present the industry has grown steadily. At the present time the industry is on a substantial, profitable basis, far beyond the dreams of the pioneers of the district.

The natural advantages of the Orange county section are: richness of soil; artesian wells, to be had at a depth of 100 feet, which furnish an abundance of pure water, that is very essential in growing celery; climate perfect, situated as it is on the coast, with the ocean breeze by day and fogs by night. The winters are also desirable, as the thermometer very seldom drops below the freezing point—in fact, being on the coast, it is afforded an even climate. We attribute as much to the climate as to the peculiar nature of the soil.

The consumption of celery has increased surprisingly in recent years, and the demand is fully equal to the supply.

CURRENT EVENTS.

Opposing the Rule.—The new rule of the Postmaster-General permitting mail matter to be sent in rural districts, by number, is creating much dissatisfaction, it seems, among merchants in the districts affected by the order. The large business houses are sending their catalogues out to individual addresses by number and it is claimed orders are being sent these houses for goods, which of right should be sold by the country merchants.

In the household department, this work, a lady writes commending the system of mail orders. She thinks it fine for farmers' wives who are thus enabled to get what they need from the city stores without taking the time to go for them. It will be seen that from the view of the farmers' wife the scheme is all right, but from the standpoint of the merchants it is all wrong.

In the old countries where the package delivery system obtains, it is immensely popular with the common people. It will grow to be popular in this country, as its scope enlarges, but it will seriously cripple merchants in the rural districts.

The question is a delicate one to solve, for while it may be answered in the affirmative for one class, it is a negative proposition for the other. But we anticipate that the rule will remain in force. It is a progressive one and this is emphatically a progressive administration.

* * *

A Fine Appointment.—President Wheeler has just appointed Mr. J. B. Neff, of Anaheim, as a conductor of Farmers Institutes in Southern California. Mr. Neff is a well-known fruit grower of Orange county and has been for years, a leader in the local association of walnut growers and manager of the Southern California Deciduous Fruit Exchange. He has also been prominent as a speaker at Farmers' Institutes in Southern California and is thoroughly in sympathy with University extension in agricultural lines and will proceed energetically in organizing meetings to be held during the coming winter and spring. Mr. Neff's residence at Anaheim will be of advantage in his work as it is a central location in a county of notable agricultural specialities, as well as greatly diversified agriculture. All localities in the counties south of the Tehachapi mountains desiring Farmers' Institutes are invited to correspond directly with Mr. Neff.

* * *

The President a Hummer.—President Roosevelt is the only president the country has ever had who will have visited every state in the Union during his term of office.

With the wind-up of his southern trip he leaves but one State untouched and he declares he will tread the soil of this one before the expiration of the year.

The remarkable homage paid the President in the south is a record breaker. It has surpassed that of Lincoln, or Grant, when these men were central figures in the most trying periods of the nation's history—not in the south of course—but in the north where the enormity of their services were felt and by a grateful people appreciated.

But Roosevelt has gone into the enemies' country, battered down the walls of party strife and sectional hatred, and won to his embrace a people who never before loved a northern president. He has talked to hundreds of thousands about their duty as citizens, urging them to the highest value of progress and good fellowship and condemning any hatred of factions or race prejudices. And at the last these people have heard and embraced his doctrines. Booker Washington says "his coming breaks the dawn of a new day for the black men of the south."

Let us hope from this day forth, no occasion may ever arise when the comity of love and goodfellowship breathed by the President upon both north and south shall be broken, but as one country, under one flag we shall march on to that high destiny intended for the Republic from the beginning.

* * *

Sacramento Valley to be Irrigated.—The Senate Chamber of California's Capitol at Sacramento was the scene on October 21st of an irrigation meeting of unusual importance. It was a convention of Sacramento Valley people called for the purpose of considering plans for developing what is declared by leading engineers to be the greatest irrigation opportunity on the American continent.

Governor George C. Pardee, of California, who is also President of the National Irrigation Congress, presided at the meeting, which was called by the Sacramento Valley Development Association, an organization of Sacramento Valley counties. Men prominent in State and National affairs were there, leading citizens from every portion of the valley, representing large private interests, counties, municipalities, and organized commercial and improvement bodies.

The result of the meeting was a strong declaration for united effort by the people of the entire valley to bring about the early construction of some portion of what the officials of the Reclamation Service call "the great Sacramento Valley Irrigation Project." A resolution was unanimously adopted pledging the united support of the entire valley to such locality as may be selected by the engineers of the Reclamation Service as the proper place of beginning.

* * *

Japs Leaving the Country.—The Pacific Coast is threatened with an exodus of its Japanese people. They see a grand future in the territory now ceded to the Mikado in the terms of settlement between Russia and Japan, and with the keen perception which is characteristic of the race they are hustling to improve their opportunity.

Already more than one hundred prominent Americanized Japanese have sailed away to return to this land no more and it is said the outgoing tide has only just begun, and that its results will be to carry out from California the most of the present Japanese population, and particularly the best of the Japanese business men. They declare that not for many years at least, will the Japanese immigration again head toward this coast.

Manchuria and Korea are the lands of promise which lure the Americanized Japs. It is also the loadstone which is attracting the men who otherwise would come to California.

In those countries, say the Japanese there is ample opportunity for all the overflow of population of the Mikado's empire. The natural resources are practically undeveloped, and both in agriculture and in business channels are already opened to the enterprising Japanese opportunities which look inviting.

The cable despatches have told from time to time of the sending of great numbers of the soldiers to Manchuria, where they are to resume their civilian lives. This class, mostly, are common laborers, with a little advantage from their military experiences and the broadened experiences thus gained.

A certain percentage of the business and professional men of Japan are going to the two countries mentioned: but to the ambitious Americanized Japanese the field opens with even better promise.

Western methods and western machinery are used in nearly all the large enterprises. In this the men who have been here, and who have had the advantage of several years of familiarity with these methods, have a great advantage. They are not slow to see the opportunity.

With the going out of the skilled Japanese domestic and floriculturist this coast will feel the loss. Who will be found to supply the deficiency is not apparent at this time. California will need skilled workmen. The agricultural colleges of this state, and the coast, should be turning out accomplished floriculturists and gardeners to supply the places of our foreign workmen.

* * *

The Empire Rent.—Russia is still the storm center of the world. The close of the Japanese-Russia war transfered the scene of conflict from the battlefields of Manchuria and the north to the inland country of the Empire. Not since the fall of the French Kingdom has such a mighty revolution stirred any country as that which is raging today in benighted Russia. We use the term benighted in its broadest sense for it is to be doubted if in a territory so broad as that possessed by the Czar of all the Russians, there is to be found the same per cent. of illiteracy as exists within that realm.

From one end of the Empire to the other revolution is rampant, life and property are in jeopardy and "uneasy rests the head" of the monarch of the Empire.

Why is this thus?

Because the people are demanding that the shackles of bondage which have been forged about them since the Empire was founded shall be stricken off. That liberty of thought and education shall be allowed free scope, that the common rights of God's sons and daughters shall be permitted to a race too long held in slavery.

What is to be the result?

The Empire will fall unless the rights of the people are encouraged. The Czar and his advisors will go down in the earthquake of public indignation unless he rises to the demands of the hour and makes his Empire one where liberty abounds. Today all the commercial and industrial interests of the country are paralyzed. The people are enraged, and the government is impotent to stop the progress of internal dissension. The hope of Russia's future rests alone with the Czar, and he is but a child in the hands of the implacable enemies of civilization.

Premier Witte has recommended the elective franchise for the people, participation in legislation and the abolishing of martial law. The telegraph dispatches now say the Czar has granted in part, the wishes of his subjects. It is to be hoped the report is true. The people do not appear to have faith in the manifesto, they doubt the sincerity of Nicholas in granting civil liberty for up to the present hour he has never shown that he could rise above the mandates of his autocratic advisors. In the meantime the world waits in anticipation the final determination of events.

* * *

Result of the Chinese Boycott.—The feeling of the Chinese people toward America is shown in the action of the natives this week, in an attack made on Rear Admiral Train, Commander-in-chief of the American Asiatic squadron outside of Nankin. The Admiral in shooting pheasant, accidently hit a woman, whereat, hundreds of natives surrounded the Admiral, knocked him down and took from him his gun. Lieut. Train, who was with him was held as hostage.

The affair may create international complications, for the ugly disposition heretofore exhibited by the Chinese in waging a boycott war upon American goods shipped into China shows the temper of the natives. Of course the accident is to be deplored, but the subsequent conduct of the natives only shows the condition of the public mind and how small a matter may kindle international complications and possibly render it necessary for this government to administer a caustic reproof to the irate heathen.

NEWS OF COUNTRY LIFE IN THE GOLDEN WEST

HORTICULTURE.

Riverside has shipped this season, nearly 6000 carloads of oranges and lemons.

Newton Pippins of this year's crop shipped from the Pajaro valley are selling from $3.60 to $2.85 a box in London.

Nearly 1000 carloads of fruit have been shipped from Vacaville this season, a heavy gain over the shipments of 1904.

As the prune market is badly off color at present there is nothing doing in Pajaro valley prunes. The bulk of the crop is in the hands of the growers.

There is a rapidly growing demand for California grape syrup, and the Tulare county factory expect to enlarge the capacity of their plant as soon as possible.

Professors Waite and Smith of the University of California have started a thorough campaign against the pear blight in Northern California, beginning their campaign about Redding.

The Fullerton Walnut Growers' Association has opened its packing-house and will move two cars this week. The association estimates its output for the season at forty cars.

The first carload of navel oranges, ripe and well-colored, were shipped from Lincoln, Placer county on Oct. 16th. This was probably the first shipment in the state.

One of the largest Placer county orange growers has made a careful study of the total cost of producing a box of navel oranges up to the packing-house and computes it at eighty cents.

The Orange Growers' Cash Association has let the contract to J. W. Carroll for a new packing house at Highgrove. It will be built on the line of the Southern Pacific and will cost complete $3950.

The Arlington Heights Fruit Company has received $1923 net for a car of 312 boxes of Squirrel and Palm brands of lemons. The sale was made in Providence. Another car brought $1917 in New York.

The total shipments last season to last Saturday were 29,845 carloads, of which 4250 were lemons, a total of 25,595 carloads of oranges from Southern California alone. The total amount of money involved was $23,756,000.

Close on to 40 tons of table grapes and late peaches have been shipped by Wells-Fargo express from Hemet and San Jacinto during the past month, and for next year the parties who are shipping prophesy about double that amount.

One thousand carloads of grapes have been shipped from Lodi thus far this season of which sixty per cent. were table grapes and forty per cent. wine grapes. Four hundred tons of grapes have been crushed at the winery.

John Isaac, Secretary of the State Horticultural Commission, has received a communication from Professor M. B. Waite of Washington accepting an invitation to read a paper on pear blight before the Horticultural Convention at Santa Rosa.

Hop and vineyard growers have been unusually fortunate this year in being able to harvest their crop without the interference of rain. This is the first season for some years that grape men did not have to contend with rain and possibly suffer loss to their crops.

Recent advices from Hood River, Oregon, state that Newtown Pippins are bringing $2.50 per box f. o. b. at that place, and Spitzenbergs are commanding $3.00 per box. This price for Spitzenbergs is an advance of 75 cents per box over last season's prices.

Shippers of Bartlett pears to Europe have not had much besides their labor to pay them for their pains of late. Cables from the other side recorded a big slump in this week's market. About 8000 boxes sold ex. Ss. Campania averaged only 40 cents per box, and about 2000 boxes ex. Ss. Baltic average 42 cents.

Late prices for California grapes in New York have been: Tokays $1.35 to $2.25, average $1.75; uniform crates $1.25 to $1.50, average $1.47; Cornichons $1.40 to $1.70, average $1.65. A car from Holly sold for $1707; two from Lodi for $1664 and $1630, and one from Mayhews for $1683.

There are 25,000 acres of grape vines in Sonoma county, valued at $5,000,000. The annual production of wine in the county is about $15,000,000 gallons which is equivalent to 100,000 tons of grapes, or an average of about 600 gallons of wine to the acre of vines. The annual output of wine in Sonoma county for the last ten years is 7,000,000 gallons.

The Fullerton Walnut Growers' Association has opened its packing-house and moved two cars last week. The association estimates its output for the season at forty cars. The Benchley Fruit Company is moving the crop of the Golden Belt Company and sent out three cars during the week, and will send between twenty-five and thirty cars for the season.

Two cars of oranges were shipped from Rocklin, Placer county, to San Francisco, for Australia, where Placer county oranges are in great demand. Placer county and Rocklin orchards in particular have carried off the palm for the first navel oranges shipped this year, sixteen boxes being shipped on October 14th, although not as well colored as they are now, and were quickly sold for $5 per box. Since October 14th oranges have been steadily going into the San Francisco market from the lower foothills of this section.

AGRICULTURE.

Fall cantaloupes are being shipped daily from Thermal.

The late potato growers in the Pajaro valley would welcome a good rain now as it would save their potatoes from the ravages of worms, which are getting numerous, especially in the heavy black lands.

As a profitable industry when it is properly looked after cantaloupe growing in Tulare county is highly satisfactory. The crop gathered from a 35-acre field aggregated 10 carloads, the receipts for the same netting over $5000.

It is said a Riverside man has originated a melon which is pronounced of superior flavor and which is said to be an uncommonly good keeper. It bears resemblance to the cantaloupe and to the casaba melon. The average weight is about six pounds and in one of that size the space occupied by seeds is only about an inch in diameter. The pulp is solid all the way from the seed space to the rind, and is nearly all edible. The melon is long and egg-shaped and when ripe is liberally striped with yellow.

One of the Cultivator staff writing from San Luis Obispo, says: "Crops around here are good—wheat damaged a little by rust, but not seriously. Barley is good, hay plentiful, beans under cover. Stock and dairy flourishing. Many new settlers coming here and the whole community is prosperous. The factory closed after the most successful run in its history. The first beets were hauled on July 11, the first beets ground on July 17, and the first sugar beets two days later. This season's run is one hundred and one days.

LIVE STOCK.

E. R. Sargent of Cloverdale, Wash., has a spring pullet that was hatched in April that has laid 14 eggs and brought out 11 chickens this fall. How is that for irrigation?

The Board of Supervisors of San Francisco have appropriated $925 for an expert investigation of the city's milk supply by professors of the University of California. The investigation will be independent of the local Board of Health.

The Cloverdale wool sale Tuesday did not realize within two cents that paid at the Ukiah sale last week. At Ukiah the top notch figure was 18 1-2 while Cloverdale paid only 16 1-2. Most of the wool was sold, but the growers feel that a higher figure should have been paid.

San Francisco's dairies are getting into trouble, out of eighty-nine samples of milk analyzed, three contained coal tar dyes, two were adulterated with borax, many showed the presence of poisons and disease germs, chemically known as staphylococci, diplococci and streptococci. Not one of these samples was free from detritus, which is another name for dirt. A few samples were deficient in butter-fat.

MISCELLANEOUS.

During the coming winter and spring many miles of trails will be built in the government forest reserves in California.

The express shipments for last week from Escondido were 900 dozen eggs, 1360 pounds chicken, 555 pounds cream and 520 pounds butter.

The Palo Alto Board of Trade has prepared a "Tree Planting Ordinance" to be presented to the Town Trustees, to the end that a systematic plan of beautifying the town might be followed.

The Farmers' Institute held in Corning last Monday was a gratifying success in every way, and afforded its promoters much satisfaction and pleasure. The three sessions were well attended, over 450 being present at the evening session.

The culture of mushrooms is to be experimented upon by L. C. Gordon, of Boulder Creek, Santa Clara county. He is preparing 4000 square feet of beds of composite made up principally of stable manure. If this experiment proves successful he intends to build proper mushroom cellars and enter into the business extensively.

Elwood Cooper, President of the State Horticultural Commission, has issued a circular invitation to all fruit growers, packers, nurserymen and others interested in horticulture, to attend the thirty-first annual convention of fruit growers, to be held in Santa Rosa Tuesday to Friday, December 5th to 8th, inclusive.

U. S. Department of Agriculture, Climate and Crop Bulletin of the Weather Bureau, California Section, for the week ending Monday, Oct. 30.

General Summary—Generally clear weather prevailed during the past week, with dense fogs along the central and northern coasts during the night. Light frosts occurred in some sections, but caused no damage. Throughout the interior of the State the conditions were excellent for fruit drying and raisin making and both have been brought to a close. An average crop of raisins of superior quality has been harvested. Wineries continue to run to their full capacity in the San Joaquin valley. The harvest of Tokay grapes in the American river district is completed.

Citrus fruits are making good growth in all sections. Oranges are maturing rapidly in the San Joaquin and Sacramento valleys and a large crop of superior quality will be harvested. The first carload of oranges of the 1905 crop was shipped from Exeter, Tulare county, on the 28th. Shipments will be general within a week. Olive picking has begun and the crop promises to be large one. A large crop of apples of excellent quality is being harvested in Humboldt county. Bean thrashing continues; the crop is large and of good quality. Large shipments of hay continue. Hay baling is completed in all sections and a large crop was harvested. Walnut harvest continues. The yield will generally be much less than was expected, and the crop light.

Dry plowing and seeding are progressing in most sections. Dry feed is getting scarce in some districts. Rain is badly needed in all portions of the State to start the new feed and put the ground in condition for plowing.

* * *

Eureka Summary.—Dense fog along the coast the greater portion of the week; warm and dry in the interior where rain is much needed. Feed short and cattle falling off rapidly. All crops harvested except late potatoes.

* * *

Los Angeles Summary.—Walnut harvest still in progress; crop is fine, but late. Citrus orchards are in fine condition; oranges are splitting some. Peas are being largely sown for cover. Raisins in the southern districts are safely housed. Vegetables are doing well.

C. H. SESSIONS, ASSOCIATE EDITOR

A PROFITABLE DAIRY FARM.

On August 1st Prof. W. J. Spillman, of the United States Department of Agriculture, Washington, D. C., delivered an address before the farmers at Columbia and discussed at length diversified farming, and especially the profits of stock raising and dairying. In this address he stated that possibly the second best dairy farm in the United States was located at Commerce, Ga., and owned by W. L. Williamson of that town. Commerce is on the branch line of the Southern Railway in northeastern Georgia, running from Lula to Athens. The soil there is the typical red clay of northern Georgia, and the land is similar to that which usually sells from $10 to $20 per acre. What Mr. Williamson has done in dairy farming shows what can be done in a section of country where the industry is still almost undeveloped.

The farm contains about 400 acres, but only 135 acres are in cultivation, the balance consisting of 100 acres in Bermuda and 100 acres in woodland pasture (Bermuda and Lespedeza). The crops in cultivation are about fifty acres in peas, and about seventy acres in corn and four acres of alfalfa. The corn is grown for silage and the peas for hay. The corn silage consists of three parts corn and one part sorghum, so planted that when cutting the row there is no necessity of mixing in the cane. The corn is planted in four foot rows, twenty inches in drill. As soon as the corn is cut off for silage the land is sown in rye, and furnishes winter pasturage. The land where the peas are sown is also sown in rye after the peas are taken off. This rye is sown from September 15th to November 15th, and the rye is taken for pasture within six weeks after sowing. In the spring, when the rye is about knee high, it is cut and fed green to the cattle. This cutting and feeding goes on until the rye gets in bloom. Then part of the rye is cut for hay and another portion set apart for seed. Where the rye has been cut to be fed green sorghum is planted for an early feed. Where the rye has been cut for hay, the land is sown in peas, and after the portion that has been set apart for seed rye has been cut, the land is planted in silage corn. In other words, the crop rotation is as follows: Corn followed by rye, rye by cow peas, then rye, then corn and then repeat the rotation of the crop. Occasionally rye is plowed under green, and this is to keep crops growing on the land all the time, both winter and summer.

The farm is located on a rolling and partly hilly plantation. Yet there is no terrace or wash on the place. The soil is plowed deep so as to hold the winter rains, and then the crops are cultivated on a level. From ten to twelve tons of silage are cut per acre. Prof. Spillman says that the average from good farms in Illinois is about seven tons; at least it is stated in a bulletin issued from that State that the average is from five to eight tons. As soon as the silage crops are cut they are carried to the barn, where they are run through a cutting machine which cuts up the corn and cane stalks in small pieces one-half to three-fourth inches in length. There are three silos at the barn, two small ones having a capacity of 100 tons each, and one large one with a capacity of 320 tons. The cost of producing a ton of silage and putting it into the silo is from $1 to $1.25 per ton.

The cattle are also fed cotton seed meal, corn meal and bran, the plan being to feed each cow a mixture consisting of three parts each of these ingredients, giving the cow one pound of this mixture per day for every pound of butter she makes during the week; that is, if the cow makes seven pounds of butter each week, she is fed seven pounds of this mixture each day. If a cow is fed six pounds of this mixture each day she should have twenty-five pounds of silage and eight pounds of dry hay. If alfalfa hay is fed, the grain mixture can be cut in half, or in fact, can be omitted altogether.

At the present time there are on this farm 145 head of cattle, consisting of seventy-five milch cows, mostly Jersey and grades, three Jersey bulls, dry cattle and calves. These cattle are housed in the barn at night and the droppings hauled out in the morning and scattered over the land each day. At the cattle barn three men are regularly employed to clean up the premises, look after the feeding and assist in the milking. The milking is done by these three men and three boys who assist at milking time. The cows are groomed by brushing and rubbing thoroughly. They are then milked and fed. It requires about an hour and a half to milk and thirty minutes to feed. Water is suplied by tank and windmill, and there is a drinking place between every two stalls. All these drinking tubs are on a level and are supplied with water by an automatic arrangement. The products sold consist of butter and sweet milk. About $150 worth of milk is sold in Commerce, which is a town of about 2,500. About eighty pounds of butter are made each day and this is contracted for by an Atlanta firm, and nets Mr. Williamson twenty-five cents per pound. Nearly 25,000 pounds of butter are made from this dairy herd annually, and in addition Mr. Williamson buys milk enough to make 25,000 pounds. From these figures it will be noted that the sale of butter annually aggregates about $12,500, the milk about $1,800, giving a total of $14,300. The gross income from this farm in 1903 was about $5,500, or at the rate of $41 per acre for all the land in cultivation. The net income that year was about $23 per acre. The farming is done much better now, and from figures furnished by Prof. Spillman the indications are that the gross income this year will be from the 135 acres in cultivation, about $67 per acre, or a net income of about $49 per acre. Mr. Williamson pays his butter maker $30 per month, the other helpers around the barn $13 to $15. Sweet milk is sold locally at 15 cents per gallon.

THE MILKING QUALITY.

The fixedness of the amount of fat in a cow's milk makes it necessary to watch the breeding, for by a change of blood we can lower or raise it in one generation very markedly. The slight increase in butter fat, the second year that a cow is in milking, often deceives people into thinking that this is not true, but this rise is due to the superior care and feeding a cow receives in enabling her to reach her limit for the concentrated food gives her all she can assimilate of milk producing food. In the Holstein the change of form is often marked, the heifers sometimes are so coarse and beefy that one is a little ashamed of them, but when they have had their second calves they come to the milk form rapidly and make good cows. Several that were of this type are now in the Advanced Registry with creditable official records.

The milking of cows is of as much importance as the feeding. Where one has a large herd, a prize of a dollar a week to the milkers whose cows do the best, when the milk is on the increase, or whose cows fall off the least, when the milk is decreasing, gives good results. One of our neighbors thought he would try this plan. He also ran a hotel in town, which the home farm supplies with milk. At length, the cook remonstrated with him, as the milk was growing thinner every day. There was no foreman over the milkers, and they found the pump very handy to increase the milk yield.

There is a serious loss in allowing the cows to go dry too soon, and to remain dry for several months. Six weeks is long enough for a cow to be out of milking, and heifers must be milked up to this time if they only give a quart a day, or else each time they freshen they will go dry at the same period. We never believe in

Sharples TUBULAR CREAM SEPARATORS

We want you to know Tubular Cream Separators as they are

Investigate the low can and enclosed gears. Tubulars have neither oil cups, tubes, nor holes—they oil themselves. **They have bowls without complicated inside parts—hold the world's record for clean skimming, durability, capacity, easy turning and easy washing**—save half the work—greatly increase the amount and quality of butter—are wholly unlike all other separators. Write for catalog R-200

THE SHARPLES SEPARATOR CO.,
Toronto, Can. West Chester, Pa. Chicago, Ill.

CLIFFORD'S ANTI LUMP JAW

Lump Jaw can be cured. We mean exactly what we say—there are no "ifs" or "buts" about it. Our firm's name and good reputation are far too precious for us to risk them by misrepresentation. We do not ask you to take any chances in purchasing **"Clifford's Anti Lump Jaw"**—our guarantee of "no cure, your money back" goes with every bottle. We sell either direct or through agents. Price $2.00 per bottle, postpaid.

Our **Hog Cholera Remedy is guaranteed to cure**. Send $1 00 for sample package, full directions enclosed, prepaid, that will check the disease in 12 or more hogs.

Inventors and sole proprietors of Clifford's Medicated Nest Egg. Will kill all vermin. Our **Chicken Cholera and Roup Remedy** will cure all diseases that the feathered fowl is heir to.

RIVERSIDE RANCH ON ROUGH AND READY ISLAND NEAR STOCKTON 884 James Flood Bldg., San Francisco

When writing advertisers mention Cultivator.

forceful drying off of cows, by giving them alum internally, or by starving them, or by rubbing camphor on the udder; any of these ways of stopping the secretion of milk should be looked on with suspicion. Nature knows best and it is safer to follow her indications. We feed the cows right along; if they go dry before calving we allow them to do so, but without any drop below a gallon of milk at a milking, they are milked regularly without any attempt to dry them off. The idea that milking the cow stunts the calf does not hold good if the cow is fed. Of course, if the cow is starved she will drop a feeble calf. This is not theory, but learned by hard experience and the spoiling of a few cows. Some extra good cows that we sold fell into the hands of a theorist and he forcibly dried off some of them, so that they have not recovered their full milk flow. One cow that at full flow of milk gave 75 pounds has only a record of 50. She has made three pounds of butter a day; now her highest record is only a little over two pounds. Forcible drying off will ruin many Durhams, Ayrshire and Holstein cows, or any cows that are giving a large volume of milk.

* * *

The older dairymen were wise in insisting on stripping the cows. We have had to come to it, as a practical necessity, for it is easier to have one good head milker that by stripping the cows can keep the other men milking clean, for where the stripper comes along any slackness is at once discovered.

The time spent in stripping is fully paid for by the extra fat obtained. As the cows are usually left by the ordinary milker, each cow will strip from three-quarters to a pound of milk. This milk averages 7.5 per cent of fat, so that on a string of thirty cows, there is 15 to 30 pounds of 7.5 per cent milk; this equals a daily loss of 2 to 2¼ pounds of butter fat, worth say twenty cents a pound, or 40 to 45 cents.

The Hegelund method of increasing the milk flow has been tried by the Cornell and Wisconsin stations, and bulletins issued telling the results and making comparisons with the ordinary forms of stripping, without going into the details, that would be hard to describe, it may be briefly said that the Heguland method is a series of manipulations or massage of the udder that can best be studied from the illustrations in the bulletins. The average increase of milk was one pound a day per cow, the average of the fat of the entire milk was 4.29 and this last pound of milk obtained had 10.32 per cent of butter fat. The time required to obtain this last milk was from two to three minutes or twenty cows an hour. So that twenty cows will yield an increase of two pounds of butter fat worth 40 cents. When it came to careful stripping, done with the whole hand and not with the thumb and finger, the results were nearly the same. Either way was well worth practicing, for it not only increases the immediate milk flow, but also makes the period longer, before the natural decrease in the milk flow.

The best cows naturally receive the best care, and most careful milking, and while we can hardly look for many more pounds of butter fat, from the individual cow, it is reason able to hope for more cows with a capacity of twenty-five or thirty pounds of butter a week. The perfecting of the milking machine will be the dairyman's millenium. Yet there will always be physical difficulties to overcome. In my own dairy two heifers may be equally well bred, both have same care; one makes a cow giving three hundred and fifty pounds of butter fat in the year while the other gives five hundred. Now where is the difference? The two principal ones seem to be, first, in the teats; they are either too small, or too large, or too thick at the top, so there is dificulty in milking clean and the cow is never developed to her full capacity. The other cause of failure is nervousness. The fretting, easily annoyed cow is never worth as much as the placid one. Watch them going into the stable. One cow rushes ahead, blunders into the wrong stall, while the heavy producing cow walks in quietly; finding Madame Blunder in her stall, she pauses to see if a man is around to put out the intruder. If she sees no one, she walks into the next vacant stall and goes to eating, while the fussy cow frets because she is being milked out of turn. She is decreasing her milk flow all the while by her own perversity, while old Placid is enjoying her feed and thinking how much time she will have before the milker will say, "Si! Stand over!" which means, stand still to be milked.

* * *

How much there is in this nervousness can be judged by the decrease in milk flow if the herd is startled in any way. We had a heavy wind come up as the cows were going into the barn one evening. A storage shed outside of the cow yard was unroofed and collapsed with a terriffic crash. The morning milk had been forty-five ten-gallon cans; that night there were thirty-four cans, or eleven ten-gallon cans shortage. The milk was not secreted, and was lost, for the next morning there was still twelve gallons short, so the total loss of 122 gallons of milk, all from nervous shock. Now this also shows the mischief an unruly cow may do if in the barn with quiet ones. Milk is not all the value we receive from the dairy herd. In Germany herds of cattle are fattened without other thought of profit than the manure for the vineyards. This manure should pay for the food purchased. We know the heavy crops of grapes we have are due to the heavy fertilization that the vineyards have received in the past years. When our neighbor on a vineyard less than ours told us he had expended $1200 for bone and blood meal, we thought of how many cows this would have fed. So the fertilizer money will pay the feed bill, and with a little experience in feeding, the skim milk should make the returns from the pigs enough to meet the cost of milking. This leaves the butter free of expense, and selling only fat, there is no loss of the fertility of the soil.

* * *

The wonderful success of Mr. Dietrich of Flourtown, Penn., is told in this year's Department of Agriculture Year Book, and should be carefully studied. He has thirty head of stock on 13 acres of land, 17 milking cows 8 heifers of all ages, from springers to calves, three bulls and two horses. All the hay and fodder used is raised on the farm and 3300 pounds of hay were sold. Professor Stillman particularly speaks of the herd as being well kept and in good order. In 1881 this farm was so run down that it could not furnish roughage enough to feed two cows and a horse. Dr. Dietrich has neither purchased manure nor commercial fertilizers. The cows are kept in the barn and the crops of feed cut and hauled to them. Two silos of sixty tons each are filled with corn grown on the farm. The stables have cement floors and all manure is saved and hauled out daily and spread on the land. Dr. Dietrich is to write about the soiling crops he grows in the next Government Year Book. About $400 is spent each year for commercial feeds for the stock. The corn grown for silage on this highly fertilized land produced thirty tons to the acre. So Dr. A. T. Neal of the Delaware station estimated. Now why has this little Flourtown farm and its owner been so successful? Because Rev. Mr. Dietrich read everything he could find, that was on this line of work, and he applied to the farm everything that appealed to his common sense as reasonable. The soil of this farm by recent analysis contained 20,000,000 of bacteria to 1-30 of a cubic inch of soil.

It has been suggested that some time in the future we may sell and buy our farm lands by the bacterial count. Dairymen have been so unmercifully used by the schemers on these bacterial counts that they certainly would not welcome it in any guise. It is a pleasure, however, to see in Mr. Dietrich's success the triumph of book farming, to see recognized the work of the scientific corps of the universities and experiment stations, that it is practical and not all theory when applied to the soil. The return to the soil is a hopeful sign of the times, for it indicates that at last educated people are finding pleasure in doing as well as in thinking, "for he that can work is born king of something."—Mrs. M. E. Sherman.

AN ARKANSAS TRIBUTE TO THE MULE.

The mule will keep up his end of the doubletree on one-fourth less grain than the horse, because he masticates his food much better.

He can stand much heat. If given his natural gait he will do a good day's work the hottest day we ever have.

He observes the rules of health better than most men by not overloading his stomach with food and drink—especially while too warm is he abstemious.

If the hired man neglects to close the corn crib door the mule is the first one to notice it. He pokes his head inside, picks off what shucks he can find and nibbles at a few ears of corn. He won't lie down nor take a wink of sleep, but stays right there and guards that crib all night, knowing if the horse be allowed the chance he will eat enough to kill his fool self.

He is seldom if ever sick, but should he become so, turn him out at once on the prairie and in the brush and he will prescribe for his own case.

He will save you the expense of a currycomb, the time spent in using it, and be very much obliged to you besides if you will just let him roll all he wants to after the day's work is done.

If you do not try to break his neck by high checking, he will sometimes walk a little sidewise or carry his head low or in some position to favor a coming collar sore. It is a positive fact that an Arkansawyer's mule team will will go through a four month's hay harvest pulling a six-foot

mower with no reins to the bridle and just the top hame string for a collar pad without a pimple. All this side by side with the Illinois man's horses checked up until they have the neckache besides a sore on top of their necks as raw and red as any slice of old horse bologna you ever ate at a public sale free lunch.

We never hear of a mule trying to commit suicide by running into an old well or barbed wire fence. Give him a little time to investigate the mudhole that you are driving through, or over the bridge with a weak plank, and he will not finish by breaking the plank or a leg, either. If he runs off, he does not do it for meanness, just to wake up and keep from going to sleep. He never runs far, scarcely ever breaks a thing, and never gets scared about it.

There are two ways of working a mule, with fifty cents expense, so that he never will run away. A mule well broke to work double can be worked with perfect safety to any tool or rig.

Don't play with and tease the young mule, but give him a kind handstroke occasionally. He will be just what you make him.

If the balky driver overloads the mule, he will try several times to pull the load, but when he finds out there is no use wasting strength, he quits. However, he won't rear up in the air, paw the earth, or hang his head ove. his mate's neck, but simply stands still till the load is lightened.—then he starts both load and old Norman.

When the heavy hauling and all the summer work is done, you can turn the mule out to rustle through the winter, if your conscience will let you. On the other hand, the old mule will pull through the winter, scarcely losing a pound, but if the old Norman should, his hip bones would make a good hatrack. Such a life many a mule has led for more than forty years. For these reasons I believe the mule is the best animal power we can have on the farm.—C. Foster, Stuttgart, Arkansas.

BUTTER PACKAGE MARKING.

The arrest last week of one of the leading grocers in the City of Los Angeles for violation of the above entitled statute, passed by the last legislature and now a law in full force, marks the opening of a most vigorous campaign by the State Dairy Bureau.

It has been the custom of the packers, it appears, to fail to correctly mark their packages, some being an ounce short in weight and others so marked as to confuse the buyer as to the exact amount he is paying for.

Complaint was made to the State Dairy Bureau, and parties who were known to be violating the law were informed that they must comply with the State regulation for proper marking butter. Declining to do this, arrest has been made of one offender and others are to follow.

To the complaint of the inspection, the defendant has entered a general demurrer, setting up in his answer the unconstitutionality of the law. It is well to remember that the State Dairy Bureau is in control of this matter and from now on will campaign the State to arrest every violator of the butter marking law. The law appeared March 20, 1905, and the three most essential provisions to know are the following:

Section 1. No person or persons, firms or corporations by themselves or their agents or employes, shall sell, manufacture or prepare for sale, offer for sale or expose for sale, or have in his or their possession for sale, or consign, ship or present to any dealer, any butter in packages containing less than six pounds and more than one-half pound, unless the exact weight of such butter contained in such package or packages, rolls, prints, or other form of package, expressed in the number of pounds or ounces or in both pounds and ounces, shall be printed or durably and legibly marked upon the wrapper or other container of such butter in letters or figures, or in both letters and figures, not less than one-fourth inch high and upon the same side or face of such package upon which the producer's or seller's name and address appears, and if such name and address does not appear, the weight alone shall be legibly and durably placed upon such package in letters or figures not less than one-fourth of an inch high.

Section 2. Whoever shall violate any of the provisions or sections of this act shall be deemed guilty of a misdemeanor and upon conviction thereof shall be punished by a fine of not less than twenty dollars nor more than one hundred dollars, or by imprisonment in the county jail for not less than ten days nor more than fifty days, or both such fine and imprisonment, at the discretion of the court.

Section 3. It shall be the duty of the State Dairy Bureau, now existing under the laws of this State, to enforce the provisions of this act and to cause the prosecution of any person known to be guilty, or that it has reason to believe to be guilty, of violating any of the provisions of this act. It shall be the duty of the district attorney of each and every county in this State, upon application from the State Dairy Bureau, to attend to the prosecution in the name of the people of any action brought for the violation of the provisions of this act within his district. One half of all fines collected for the violation of any of the provisions of this act shall be paid to the county in which the fine is imposed. The other one half shall be paid to the State Dairy Bureau and by said bureau to the State treasurer and the same shall become a part of the appropriation made by law for the use of the State Dairy Bureau.

Section 4. All acts and parts of acts inconsistent with this act are hereby repealed.

Section 5. This act shall take effect sixty days after its passage.

The State Dairy Bureau is to be commended on its determination to enforce this law as it is also to be congratulated that it is hereafter to give special attention to cleanliness of dairies throughout the State.

LUMP JAW.

From interrogatories sent the Cultivator it appears that Lump Jaw is attacking the cattle in some sections of this State. It usually shows itself in the face, and needs quick attention to arrest it. The disease is infectious, and while not easily communicated from one animal to another, may yet be transmitted if a diseased animal drops any of the bacteria from the sore—if it discharges—on hay which other cattle pick up. The vegetable fibers of barley which penetrate the gums of cattle will bring on this disease.

When a lump appears on the jaw of the cow or steer it should be treated as Dr. Oliver stated last week, the animal should be separated from the balance of the herd and if the disease cannot be arrested the animal ought forthwith to be killed.

When a cow is giving a pound of butter a day, says the Farm and World, she is subjecting her nervous system to a severe strain, for she gives besides that an equal portion of almost solid protein or nitrogen in the form of casein, and she has to extract it with a very strong exercise of nervous force.

We are told that the man who can make two blades of grass grow where only one grew before is a public benefactor. How about the man that can cause his cows to make two pounds of butter where they only made one before.

When breeding sheep see that they are vigorous and healthy, so that the offspring may be sound and robust.

BY DR. W. J. OLIVER,
318 East Second St., Los Angele

To the end that this department may be made as valuable to the subscribers as possible, we ask observance of the following: Be sure to state in full the history of the case, location of the disease and the conditions under which the animal has been kept just before and since the disease ap eared. Give your name and address, which will not appear in the paper if you so request. No charge whatever is made for such questions as are answered through the colums of the Cultivator, but when an immediate mail answer is wished Dr. Oliver asks an additional fee of $1.00 and will give immediate attention and reply by mail. In such case write Dr. W. J. Oliver, 318 E. Second St., Los Angeles, Cal.

Questions should be in by Monday to be answered in the following Friday's paper.

INCURABLE.

Editor Cultivator: Will the Cultivator tell me how to straighten the ankle of my mare She hurt her knee last winter and took cold in it, since it has been double size and nearly stiff, the big cord is drawn and her foot is drawn back. It is the fore knee. If you can tell what will do it good, or straighten it, I shall be greatly obliged. A. M. H.—Yuma, Arizona.

Your case is incurable. The only treatment which would benefit your horse would be a surgical operation called tenotomy, and that would require the services of a competent veterinary surgeon.

STOMACH WORMS.

Editor Cultivator: I have a horse that has the large intestinal worms. What can I do to rid him of them?—J. H. B., Covina, Cal.

The worms you refer to are stomach worms. Treatment—Sulphate of iron, pulverized, 4 ounces; Areca nut. 3 ounces; Arsenic, 1 ounce. Mix. Dose—Heaping teaspoonful night and morning in a little damp feed.

LUMP JAW.

Editor Cultivator: About five months ago I noticed a bunch on the jaw of a heifer I have. The lump seems fast to the bone and the hide fast to the bunch. I treated it and soon after it discharged considerable. This sore never healed, but there is a foreign growth that looks like proud flesh, or of a dark bluish red color, and bleeds almost to the touch. I have put on clear carbolic acid, also burnt alum, but to no effect. There is no discharge from the sore and I can't see that the bunch is enlarging any save only, that growth from the center of it grows larger.—C. E. S., Healdsburg.

The bunch you refer to is lump jaw and is almost impossible to cure when it has reached that stage. If treatment is attempted the bunch should be dissected out and thoroughly cauterized and a little powdered bichloride of mercury appled to the wound. After 3 or 4 days the scab may be removed and another application made.

MRS. A. BASLEY, ASSOCIATE EDITOR, HOLLYWOOD, CAL.

BIDDY AND THE INCUBATOR.

Among the letters awaiting answers during my absence from home is the following, which gives such a clear description that I will print every word, for nearly all of us have been through the same trouble and can sympathize with the writer, Mrs. A. A. V., Los Gatos:

We have been reading the Cultivator for two years, but this is the first "help wanted" we have asked you to insert.

We are hatching with incubator and can get only 60 per cent to hatch, while the makers of the machine claim they hatch 90 per cent. And we have almost lived with the incubator to get it to do better, for Biddy brings 15 chicks from 17 eggs (average) from same stock. After they are out of the shell we have no further trouble except with one hatch. We bought eight dozen pure-bred B. Leghorn eggs last of May. Hatched 45 chicks. Nice looking ones, seemingly healthy in every way. Biddy hatched 16 at same time, our own stock, which we took from her and put with incubator hatched chicks. All did nicely for a few days, when a Brown Leghorn looked droopy. In a couple of hours I revisited to find its wings hanging, it standing asleep, which it continued to do until it died. And so they went until from the 45 chicks we now have five, and of the 16 W. Leghorn (Biddy's) we still have 16. In the same pen, eating of same food, in same troughs, with same care in every way. Positively no lice. The only symptoms we could see were drooping and sleeping. Some ate and some refused to eat. Some tried to eat, but seemed from weakness or something else not to be able to grasp the food. Some died quickly and some lingered until upon lifting one it seemed like only so many feathers. The first one died when about eight days old. The last one died about three weeks ago. The five remaining are nice ones (the two little roosters crowing). We thought "in bred" but breeder says no.. We could find nothing in dissecting.

What was the trouble, and what the cure? If contagious, why did not W. Leghorns have it?

We have five pullets and one cockerel of pure bred Plymouth Rock (White) from one hatch. Could I mate them together (brother and sisters) or would that be in-breeding and poor results? Their father and mother were no relation.

What was the trouble with pullet. She was a beautiful Plymouth Rock, five months old. One day at feeding I saw her pick up a few grains of wheat, then stop eating and raise her head high, twitching it in each direction as she did so; then eat again and raise her head, and continued so. She seemed not the least sick. The next morning when eating she did the same. We caught her; she was nice and fat, but her crop seemed to be almost empty, but puffed with gas. Put her head down and milk, water, etc., gushed out. Separated her from rest, gave a dose of salts; also fed her bread soaked with milk. She drank a great deal, but would not eat. After a week's treatment she seemed no better (and not much worse); no other symptoms than puffed up crop and lifting her head, and water (it was thicker than water) gushing out of her mouth, a very foul odor. I had her killed. Bled freely. The only thing found that looked unnatural was that the gizzard contained so much bright yellow fluid with plenty of grit. Was there a cure for her? If so, what? We used the hatchet as an act of mercy. We like chicken raising, but find no pleasure in chicken doctoring. But we keep things nice and clean and care for them and do not have much doctoring to do.

Answer.—It really is discouraging to have an old hen succeed where I fail, and I worked hard to discover the reason for it. I do not know what incubator Mrs. V. is using, so cannot lay my finger on the special defects of any make. Her letter indicates that it is more in the hatching than in the bringing up of the chicks that the difficulty lies, as those hatched by Biddy have all grown and are strong and vigorous.

What is the reason that Biddy hatched better than the incubator? There are quite a number of reasons for this, and by answering as fully as I can I may have to divide this article in two chapters.

The first requisite for a good hatch is good fresh eggs. Biddy's eggs were from Mrs. V.'s own yard and the hatch showed they were fresh. The vigor of the chicks indicates they inherited good constitutions from well cared for healthy parents. First, then, the eggs must be fresh; not over two weeks old, from vigorous, well-fed and properly mated parents. Well fed? What does the feeding do? Much, for the nourishment of the embryo in the shell depends on the food which went into the making of the egg, and especially the green food. When I first came to California I did not realize how little green feed there is on almost any range. The hens had eaten up the green barley and the yolks of the eggs were, I found, very pale, and the fertility low. A farmer living near explained to me that it was the lack of green feed. I appealed to friends who had lawns, and I bought alfalfa, choosing the bales that were full of leaves. I cut the alfalfa in my clover cutter and soaked it, and in about three days the eggs were the proper color and the fertility had greatly improved. Animal food at hatching time is as much needed as green food. We must as far as possible follow nature in this and give the fowls the food they would have if wild, at the natural breeding time—that is, in the springtime. Properly mated fowls, not too much in-bred, but above all, have the male vigorous. Personally I do not approve of constantly changing the males for many reasons. It keeps a spirit of unrest among the hens. I prefer mating a smaller number of hens, from eight to ten of the American breeds to one male, or from twelve to fifteen of the Mediterranean breeds, and not changing the males, but if, as I occasionally find, one hen

A BARGAIN!

Pick of 50 WHITE ROCK HENS, fancy breeding stock from leading strains. Good color, shape and weight. Free from brass. Bred for heavy egg production and some laying now. Not one is worth less than $2, a number would be cheap at $5 00 each. Am in a hurry to move them, so TAKE YOUR CHOICE AT $2 00 EACH.

BUYS THE WORLD'S FAMOUS EGG FOOD NO. 4

MIDLAND

IF YOU WANT EGGS
YOU WILL FEED NO OTHER

Used by all the largest and best breeders in the country. Thousands of poultrymen are using it, and it is the acknowledged standard of the world. Hap-hazard feeding is no longer profitable. Try Midland Food and be convinced.

Petaluma Incubators and Brooders

The acknowledged standards of perfection. All poultrymen who have used these machines have supreme confidence in their ability to hatch and brood. Hence their ever increasing popularity. Winners of the GOLD MEDAL at the St. Louis World's Fair for greatest hatch, with 40 different makes of incubators in competition. How's that?

St. Louis, Mo., Dec. 8th, 1604.—Petaluma Incubator Co., Petaluma, Cal.: My Dear Sir—The awards have been held up owing to a controversy between the Exposition officials and the national commission, but today I am able to state the award of a gold medal on your Petaluma Incubators has been confirmed. You are at liberty to make use of this in any you see fit and in due time the diploma will be issued and the medal obtainable. Congratulating you upon this evidence of the merits of your incubators, in which there was very great competition, I beg to remain, yours very truly, J. A FILCHER, Commissioner.

And Now Comes New Reward for Merit:

Read the following telegram received from the Lewis & Clark Exposition at Portland:

"Petaluma Incubators and Brooders just awarded Gold Medal at Lewis and Clark Exposition."

Prussian Poultry Food

NESTS NOW FILLED WITH EGGS.

Last year my egg crop was a failure, though I have some good breeds and give them plenty of grain, etc. In April last, on the advice of my brother-in-law in Wisconsin, I began feeding Prussian Poultry Food, and I never imagined the results. The nests have been full of eggs every day. I am still feeding it and never expect to quit. I bought a flock of common dung hills, scrubs, etc., at a sale in June and gave them the food and now they lay about as well as thoroughbreds.—G. W. Arbogast, Fisher's Grove, Iowa.

A GREAT EGG PRODUCER.

Prussian Poultry Food cured my flock of Roup all sound and well in ten days time. For keeping poultry in condition, and especially as an egg producer, it stands without an equal. I cheerfully recommend it to all poultrymen to give it a trial and become convinced. Feed as directed and you will make no mistake.—B. H. Payne, Palmesville, Ohio.

Prussian Remedy Co., Dept. B **St. Paul, Minn.**

has always infertile eggs, I mate her to another and younger spouse. The male is half the pen, and he must be vigorous and healthy and not exhausted by having too many mates. Weigh him, or simply "heft" him, lift him in your hands off the perch, and see if he is getting too thin, and feed him extra, by himself away from the hens. I had one prize winner, an especially fine bird, and to my surprise I found when I went to powder him and his harem at night, as I usually did at breeding time, that he was getting too light. After that I fed all the males extra from the pail or my hand at least once a day. That special male was very gallant; he would call up his wives and feed them and they selfishly ate his share, or at any rate all the choice morsels, the meat especially, and he, from whom the germ of the chick was to come was underfed and in a short time would have fathered weak and inferior chicks. This is another item in favor of dry feeding in hoppers. The vigor of the male gives vigor to the chicks and depends largely upon a sufficient supply of the proper food. I will finish this subject next week and tell of the other reasons why Biddy sometimes beats the incubator.

In reply to the other questions in Mrs. V.'s letter, secondly. It is usually considered better not to mate brother and sisters, but this mating is used always in making any new breed, therefore if your fowls are vigorous you can do it safely. In close-mating or in-breeding, always remember that it intensifies the qualities of a fowl or animal—the good qualities and the bad qualities. If you have a hen that is an exceedingly good layer, mate her to one of her own sons that is more of her own style than like his father, and you will probably have a large per cent of her daughters as good layers as she. The successful mating of fowls (and animals) is an interesting study.

Third. Your pullet had a bad case of what is called sour-crop. It really is indigestion, and in yards as carefully kept as yours is very rare. It comes sometimes from too great a use of stimulants or so-called egg foods, or red pepper.

* * *

EDITOR'S QUESTION BOX.

Brown Leghorns.—(Mrs. J. W. B.) Will you kindly tell me where I can get some prize stock in young B. Leghorns about two years old, for breeding purposes (males)? I am a subscriber to the Cultivator and enjoying your articles. Just now there is no such stock advertised in the Cultivator, and as I am a beginner in the business I am at a loss to know where to send.

I am experimenting with the dry feed method and thus far like it very much. It is labor saving and my chickens are in excellent condition.

Answer.—I am glad to hear that you are as a beginner trying the dry feed method, because it is the most satisfactory of all methods, but be sure to give the fowls plenty of grit and clean water.

Will some of the owners of prize stock, B. Leghorns, please send address for this subscriber, or advertise?

* * *

Feeding.—(J. N. H.) Please tell me through the columns of your valuable paper what the trouble is with my chickens and what to do for them. I have nearly 60 White Leghorn hens and I am getting from three to eight eggs each day. I feed them in the morning 1½ quarts wheat and a mash composed of three quarts of Coulson's egg food, one quart of calfalfa meal and one tablespoonful of powdered charcoal. While moulting I substituted the "moulting food instead of the egg food. For several months they have not seemed to like the mash, always eating the wheat first. If I leave out the calfalfa meal and charcoal the result is just the same. If I give a larger quantity of the mash and omit the wheat they will stand around, many of them not touching it at all, so that a portion of it remains in the troughs all day.

They have no green food except the calfalfa meal. At night I give them three quarts of wheat. They have fresh water constantly before them, also plenty of grit, bone and shell They have an abundance of shade, also free range of two-thirds of an acre of orange trees. The combs of a part of them are apparently lifeless and nearly colorless, instead of a deep colored red, as was the case a few months ago. They are free from lice and mites, and have good tent houses with ventilation at the bottom. I notice among the droppings that a small portion of them is a light yellow color and of a frothy appearance. In all other respects they appear perfectly healthy and are in good flesh.

Answer.—Your hens evidently do not like the mash you are giving them and a change will not only be beneficial but is absolutely necessary, or you will have sick fowls, in fact they are sick now.

First of all, they must have plenty of sharp grit, and clean water, besides shell, either clam or oyster, or lime of some sort to make the shell of the egg.

Then remember the rule that for every pound of hen they should have one ounce of dry grain. You are not feeding enough but you say they leave the mash; it simply shows that they do not like it. There is some ingredient in it which they dislike and for a time at least I would entirely change it. Will you try the following very simple ration, either dry or wet? I much prefer it dry for your hens. One part dry calfalfa meal, three parts bran, two parts corn meal and one part beef scraps and a little charcoal, unless you give them charcoal with the grit. You can still continue the wheat. If you have no "hopper" you can feed the dry mixture in a good deep bucket hung against a post so they will not tip it over or waste it. Feed them all they can eat, leaving it before them all day, and give them plenty of clean water, and if you have it, plenty of skim milk. I think you will find this change of diet for a month or two will be very good and that in two weeks you will have eggs.

* * *

Turkeys.—(A. L.) My turkeys have commenced to lay. Would you advise me to set the eggs at this time of the year? I tried it last winter and kept them up stairs in the barn, and I lost all but three out of 65 or 70 birds. They did well until I took them down from the barn. How should I care for them in the winter season? What diet should I give them?

Answer.—As you had such bad luck with your turkeys last winter I would advise you not to set any eggs at this

season. They require the same care and the same diet in the winter as in the summer, and it is very difficult to get the same conditions in winter. I would advise your waiting till spring-time before hatching, as you do not have the proper accommodations.

* * *

Rhode Island Reds.—(Mrs. F. A. R.) I am enclosing a postal for the name of some reliable breeder of Rhode Island Reds, also White Wyandottes. I wish to secure a setting of eggs from them.

Will you please tell me through the Cultivator columns whether Rhode Island Reds can be successfully raised in Southern California. I want them for broilers. Also what breed you prefer for that purpose? When chickens have plenty of grit is it necessary to supply oyster shell too? Please tell me how to combine the following foods to make a balanced ration for twelve hens: Corn, barley, bran, meat meal and wheat. I am using a hopper to feed the dry mash. Should barley be boiled before feeding?

Your column is such a help to me that I want to thank you for the many good suggestions it always contains.

Answer.—You will find amongst our advertisers good White Wyandottes and Rhode Island Reds. R. I. R. can be successfully grown in California and are excellent birds. The White Wyandottes are considered the best of all breeds for broilers as they are when young a plumper and prettier looking broiler and develop a few days earlier than other kinds. They do very well in California.

Of the feeds you name, corn, barley, bran, wheat and meat meal, you would find one part of each of the grains to half a part of beef scraps or meat meal very good, and in winter, or when there are but few insects and you want eggs, use instead of half a part of beef scraps one whole part. The corn should be cracked and the barley rolled. You can occasionally for a change give a little boiled or scalded barley, but do not put it in the hopper, because it will sour very quickly and make the fowls sick it kept a few days. I find that mixing the dry grains in the hopper with one part of dry calfalfa meal is excellent, and I feed the beef scraps in a separate smaller hopper or box and let the fowls help themselves.

LATE CHICKS—THEIR CARE.

Writing in the Homestead about late chicks and their care, M. M. Johnson says some good and suggestive things about climatic conditions which apply as well to California as they do to the Middle West country. The Cultivator is getting lots of letters from disappointed poultry persons who complain about the very things Mr. Johnson writes of. Our notion, apart from Mrs. Basley, or any other poultry expert is, that much of our trouble with our chickens comes from our own carelessness in tending them. But then, read what this expert says:

"I do not know of anything more seasonable to write about than the fall care of the new crop of chicks. I, as well as many others, can tell how it all happened after it is over. Let us get at it in advance. Let me say right here, though, that I am conscious of being the off-ox on many poultry matters, but it is possible that a great variety of ideas might lead to the right conclusions.

One of the every-year falling-down places is in transferring the summer broods to winter quarters. Usually we have a nice lot of pullets roosting around here and there, and our first inclination, when the first frost comes, is to gather them up and put them away snugly in their winter quarters. It's a mistake.

Let me say here and now that fowls are naturally an out-door creature. Their feathers are for no other purpose than to protect them against cold. They do not suffer from the effects of cold as quickly as we might think. Don't be in a hurry to box them up. If they have been roosting in the apple and cherry trees I venture to say that they are healthy and active, and a little cool weather only serves to fit them for real winter. After winter has come, and they occupy their winter quarters, it is better to chill them a little than to overheat them.

Many times we gather them up too early and close them up at night. Then we turn them out in the cool mornings and put them through a procedure that leads to sniffles, roup and other winter ailments, and to some extent they are invalids instead of the cackling active layers we had figured on, and there is a further possibility that roup will develop until when spring does arrive the flock as good as none.

Let me here mention the cholera, that is a tame thing as compared with roup in its rotten form. It is a first cousin to consumption with people. Both are contracted or brought on from the same causes, and both are hereditary or contagious. Yes, yes, there are cures for either, but I am here to say that money-making poultry is well poultry, and I have your "aye, aye," right now.

While there are, no doubt, reliable cures for colds, if the cause is removed, genuine roup is something to be shunned by all poultrymen, but I am straying from the chick question. Let us talk more to the point.

The usual course of things is to gather up the whole business at first frost and box them up. Pile a hundred in room enough for fifty; then we hold onto the scrubs and all till breeding time and sell the grown-up cockerels at the same or less price than they would have brought in the fall. Why not make a regular clean-up in the fall and give the good ones a better show for winter?

Now, back to the house question again. Do not close up the house too tightly until real cold weather. Don't be afraid of some fresh air. Fresh air never made consumptives. Do not curtail the amount of air; don't get the idea that air was intended to be closed out, and don't go crank on somebody's or your own ventilation plans on the hens that would kill yourself off. Ventilation is a simple thing instead of a long-headed inventive one. It is drafts of air that do the mischief. A little dampness and a little bit of draft will raise Ned every time. It is very seldom that chicks or fowls contract colds out of doors, or in an open shed that has three tight sides, and a tight roof. In either instance, the little piercing draft is obliterated.

In all my recollections I do not remember of ever seeing fowls contract a cold in a good shed, and never out of doors, unless they have been turned out of a warm place or subjected to a sudden change from wet to extreme cold and a high wind. All in all, about the same things that affect poultry affect people, or clear down the line among live stock.

Winter eggs are desirable, but my experience is that those secured through extreme methods in feeding or housing too warm are paid for dearly in some other way. I would rather get along with half the eggs if I could make sure of bringing the pullets out early in the spring in prime condition. It is not so much a question of a little cold weather as it is snow or dampness. Wet feet seem to have a direct connection with the laying organs."

OUR ENORMOUS EGG CROP.

The egg and poultry earnings of the United States for one recent year amounted to $280,000,000. Such an amount is sufficiently amazing as it stands, but you don't get its full significance until you study the relative trial. We find for instance, that the total value of gold, silver and wool and sheep produced in America during the year in question was $272,434,315. The sugar production of the country the same year was but $20,000,000. That part of the wheat crop used at home, which many consider the most valuable of our agricultural products was worth $229,000,000. The great American hog, as consumed at home and abroad brought $136,529,035. The value of the oat crop was $78,984,900. Potatoes grown in the United States were valued at nearly as large a sum as were the oats. The product of tobacco plantations was estimated to be worth $35,579,225. Cotton, the dethroned king of staples, could show only $259,161,640, as against the magnificient earnings of its feathered rival. Crops of flax, timothy, clover, millet and cane seeds, broom corn, castor beans, hay, straw and so forth, couldn't all be sold to come within a measurable distance of many millions of the poultry earnings.—Western Farmer and Dairyman.

THE INCUBATED CHICK.

(A Psychologic Tragedy.)

I'm not a little orphan, sir,
But I am just as sad,
A-peakin' and a-pinin' for
The love I never had—
One touch of human sympathy
Would melt my poultry natur',
But I refrain from hope so vain,
For ma's an incubator.

When first I burst my parent shell,
How hideous the dream—
No rich cluck, cluck fond love to tell:
No sound, alas, but—steam!
I felt in vain for sheltering wings
Within that broilin' crater;
And then, in sooth, the horrid truth—
Ma was an incubator!

I see that tin thing over there
And weep beside my brother—
"Ah, hideous lie—how much I try
I cannot call it mother!"
You say I'm false, unnatural,
Cruel as an alligator!
One can't remain quite normal when
His ma's an incubator.

Sometimes at rosy-fingered dawn
I stand in pensive mood
As now and then some kind, sweet hen
Walks proudly with her brood—
Dear influences of the home!
And I, a woman-hater,
Stand all apart with withered heart:
For ma's an incubator.

—Wallace Irwin.

THE MORNING FEED.

Fowls which are overfed in the morning are sluggish all day and become lazy and out of condition. It is exercise of muscle that creates proper functional tone. If productiveness is expected natural laws must be observed. Feed moderately in the morning, especially when the flock is small and kept in limited range.

General Agricultural Notes

A FORMER CALIFORNIAN AND HIS FLORIDA RANCH.

To the Cultivator: I was much interested in what Prof. Cook had to say in a back number of the Cultivator, as to the depredations wrought by the linnets. As usual I was happy to agree with his judgment that it is better to spare the birds than to kill them. This summer and fall I have had a demonstration of the priceless value of birds to hold our insect enemies in check. I had a fine crop of velvet beans and cow peas, but at their blossom time they were infected with the boll worm, or corn worm, which riddled the leaves to skeletons. When the crop seemed lost, along came a flock of bob-o-links, two or three hundred in number, and they cleaned up the worms of that generation to perfection. But the moths (Heliothis Armiger) were busy depositing eggs. The bob-o-links stayed three weeks and would have stayed longer but for the boys with guns. By the time the bob-o-links left, there was a new and very active brood of worms. Then came a large flock of Boat-tailed Grackles (Ruiscalus major) and these took up the good work, the worms were destroyed and the vines put on new leaves. So the crops were saved. In this climate, insects seem never to lose their activities. Fortunately we have birds that are perennial inhabitants of our fields and groves. Among the most valuable are the mocking birds, meadow larks, loggerhead shrikes, doves and sparrow, or "Kelly" hawks, the last are death to grasshoppers.

A valuable assistance to the work of the birds is the feeding habits of the skunk which is very fond of grubs and has the faculty of finding them. I have found numerous cone-shaped holes on my place which are signs of where a skunk has dug for grubs. And yet short-sighted people, or such as are ignorant of the animal, say, "kill him." As with birds of every kind, hawks and owls, included, I will not permit one of these animals to be killed on my place. Men will learn some day that animal life is here for some good and beneficent purpose and that El Senor did not make any mistake in having them here.

* * *

Florida oranges are being shipped by the car load—some twenty-five cars a day going north from the west and southwest coast alone.

What earthly use anyone can find for such green, sour stuff, is more than I can imagine, unless it is to be used in the place of lemons. They haven't the merit of green apples, for they can be cooked and made palatable with spices. Grape fruit, too, has been going north for a month. Hereabouts our fruit has only the slightest tinge of yellow. Let California possess her soul in patience and hold her oranges until they are worth the name.

* * *

The weather has a decided vigor in it this morning, 50 degrees at 5 o'clock and this reminds me of a car load of "Salamanders" which arrived this week to be used in the fine groves of John B Stetson, of Philadelphia, when the freezes sweep down on us from the frigid northwest. These salamanders are very simple and effective heaters, or furnaces, for keeping the temperature among the orange trees above the freezing point. These heaters are cylinders of heavy sheet iron 19x24 inches, and are placed over a cast iron grate which has a projecting lip all the way around on which the cylinder rests. This grate in turn is placed on bricks two at each corner of a triangle, thus raising the grate some eight inches from the ground, which admits of a free draught of air and a space for the ashes. The fuel used is coke. The salamanders are charged with kindlings of fat pine and a layer of wood over which is placed the coke.

The fuel after being placed in the cylinder is protected by a piece of sheet iron placed on the cylinder like a stove lid, to keep the rain from wetting the kindling. The cylinder has a flap or awning on its lower end made by two cuts about five inches apart and running up the cylinder about five or six inches. This permits the cut portion to be turned up and out so that rain cannot wet the fuel. These salamanders are not an experiment. They have been used here with great success.—C. J. K. Jones. Stetson, Florida.

Lands that have been pastured with sheep grow to be very rich in nitrogen. It is claimed by English farmers that 100 sheep pastured for fifteen days on an acre of land will manure it sufficiently to give a four-year rotation of crops.

If you have the "don't like to milk" feeling, don't go into the dairy business.

GO TO GARDENA.

Next to the natural resources of Gardena we know that it is proper to give as one of the most dominant factors in its growth, the energy of Mr. W. M. Gray, the propagator of the famous Gray's Gardena Dewberry, and the originator of "Go to Gardena," which has been his slogan and which has set many people to thinking and caused them to say "All right, lets go." Mr. Gray has resided in Gardena for many years and for a long time put in much hard work on his little ranch a short distance northwest of the post office. He produced great quantities of strawberries, raspberries, blackberries and ultimately discovered the merits and prolificness of the dewberry, which he introduced and proved its merits to that extent that it is widely planted all over the State, as "Gray's Gardena Dewberry."

In more recent years Mr. Gray has dropped the harder work of soil culture and is now singing the praises of the section in which he lives to the inquirer who would learn what Gardena can produce and has produced. In fact, that is one point which can be said of Mr. Gray, that he makes no statements in which the soil, the water and the climate will not bear him out. His long acquaintance with Gardena conditions fits him to give just this information to the inquirer and we may say that many people to whom he has sold home places have voluntarily said for him that without exception his statements have stood the test of time. His interests about Gardena are somewhat extensive and his desire is for its permanent upbuilding rather than for the temporary advantage of an immediate sale of real estate. His office is located near the depot where both electric lines stop and his carriages are always ready to take the possible investor over the section. He is assisted by Mr. W. H. Powers, whose several years residence fits him to intelligently sing the praises of Gardena.

"Go to Gardena and see Gray."

THE RAISIN GRAPE COMMERCIALLY.

(Continued from First Page.)

the roots of the vine, is a poor proposition, requiring an annual artificial supply of ingredients necessary for the the evaporation of this water, all of which is heavily charged with alkali, will in a short time make the upper soil incapable of sustaining any vegetable life, less hardy than Bermuda grass.

And, finally, the future of the raisin grape and the prosperity of the raisin industry will be determined by the margin of profit left to the vineyardist, over the cost of production, and we all know by experience that even when the supply does not exceed the demand, the competition among the vineyardists themselves to be the first to realize on their crop, utterly demoralizes the market, with the result that it is the impecunious grower who fixes the selling price, and that, without organization and co-operation, this is always the inevitable result.

We have today a strong organization in the California Raisin Growers' Association. With a very large crop usually to dispose of, the market has taken a full average quantity of raisins and its present requirements are supplied, but the market has been at times badly demoralized by offerings of raisins not controlled by the Association prices, which is a loss not only to the owner of these raisins but to the whole crop.

The remedy for this can be found in unanimous co-operation among producers and much better results will be attained if they stand firmly by the Association in its efforts to market the produce of the vineyards at profitable prices.

AGRICULTURE IN THE SCHOOLS.

There is none who will deny that our farmer boys and girls need to know the principles of agricultural practice. Some parents may fear that this new subject may take up too much time and interfere with regular work. But these are not real difficulties. The great trouble is to find teachers prepared to teach agriculture.

Each teacher having knowledge of the principles of agriculture is a missionary for better farming, be he man or be she woman. The errors of farm practice as seen around such teachers become most glaring. As teachers, they cannot hold their place while such things go on under their eyes.

Let it not be thought that these lessons have to do only with botany and geology and physics. They touch every side of farm life. Business accounts, farm mechanics, sewing, cooking, dairying and like topics are treated in a most instructive manner.

They will appeal to nine out of ten boys and girls. They want to know these things. Give the children the facts. They will respect farm life all the more. Such educational facts will make of them better citizens, more prosperous farmers, or healthier wives of farmers.

MAKING ASPARAGUS BEDS.

The seeds should be planted in rows about four feet apart if large quantity is to be raised, so that it may be cultivated with a horse. The seed may be planted thick so that the roots may intermingle. They should be kept growing till late in the fall when they are transplanted into the field.

Where a single row is to be planted for home use, the plants may be placed eighteen inches apart in the rows. For field culture the rows may be from six to ten feet apart and the plants from two to four feet apart each way in the rows, according to the soil and climate. The plants should be placed in the ground so that the crowns are a foot below the surface as they will gradually grow toward the surface. As the plants grow fill in the ground aroung the stems by cultivation until the ground is level at the end of the season.

As the plants are still not strong enough to force thmselves up through the one foot of soil during the first season in some situations, it is best to plow a shallow furrow over the rows before they start and work the dirt into it as before. This process will give early asparagus if other conditions are favorable as it allows the sun to get near the crowns and warm them up. Where irrigation is practiced it is best to withhold the water during the spring and late winter so as to allow the ground to warm up. This is the experience of the best growers.

On Bouldin island in the San Joaquin there are 1200 acres of asparagus in bearing, all of which is suitable for canning, and 500 acres of new planting. On Andrus island there are 600 acres, about 50 per cent. of which is suitable for canning. On Grand island there are also about 1000 acres, about 65 per cent. of which is suitable for canning. On Jersey island, about 200 acres; on Rough and Ready island, about 200 acres; on Mitchell island, about 200 acres; Pearson district, about 1000 acres in bearing. The output of Pearson district last year was about 25,000 cases; Bouldin island, about 110,000 cases, Grand island, about 25,000 cases; Sacramento 25,000 cases; Milpitas, 30,000 cases.

A FINE RANCH.

While in Gardena recently, we called at the Strawberry Park ranch of O. M. Johnson. More beautiful soil we never saw and on it is a big pumping plant which supplies several small ranches. It has a substantial residence which may be seen by an engraving on another page. And in poultry Mr. Johnson has some fine White Rocks and Bantams.

All told it's a fine home place and some day will be business property.

Waite, Bailey & Lynch, machinery merchants and engineers buy, sell, exchange, repair and install gasoline and steam engines, boilers, air compressors, power pumps, motors, etc. Otto gasoline engines, all sizes, to 200 H. P., more economical, therefore superior to all others; prices and terms that will insure due consideration. See us and be convinced. Southern California sales agents, Waite, Bailey & Lynch. Office and manufactory, 943-945 N. Main st., corner Bruno st., Los Angeles, Calif. Phone Home 1263.

Farm Lands in Kings and Tulare Counties

Unsurpassed for raising Alfalfa, Hay and Seed, and for raising and fattening Hogs, Cattle, Horses and Mules. Corn, Wheat, Grapes and Deciduous Fruits produce immense crops and large profits.

SOIL

The soil is a rich sedimentary deposit composed of tule roots, shells and silt left by the receding waters of Tulare Lake which many years ago covered these lands.

WATER SUPPLY

Sub-irrigated at about 9 feet. In one of the best Artesian Belts in the State. Fine water for stock and domestic purposes at from 35 to 65 feet. Almost an inexhaustible pumping supply at 80 to 150 feet.

PROFITS FOLLOW IMPROVEMENTS

Several Hundred Thousand Dollars now being expended on our lands for improvements.

Seven rigs now boring artesian wells.

Three steam plows turning 82 furrows and large gangs of teams now plowing and cultivating on our lands.

Thousands of acres now being prepared for planting to orchards, vineyards, alfalfa and grain.

For particulars see

Fine alfalfa lands $30 per acre and up.

Larger tracts $15 per acre and up. Easy terms. Liberal rebates for immediate improvements.

Wanted—Practical experienced farmers who fully understand alfalfa and fruit raising, to rent tracts of 40 to 160 acres. Liberal terms. Outside work can be secured while crops are growing. Must have teams and implements or some means. Houses and barns furnished.

Special excursion next Tuesday night. About one-half fare.

SECURITY LAND AND LOAN COMPANY

Home Savings Bank Building, Cor. Spring and Court Streets, Los Angeles, Cal.

WHAT HAVE WE DONE TODAY.

We shall do so much in the year to come,
But what have we done today?
We shall give our gold in a princely sum,
But what did we give today?
We shall lift the heart and dry the tear,
We shall plant a hope in the place of fear,
We shall speak the words of love and cheer,
But what did we speak today?

We shall be so kind in the after-a while,
But what have we been today?
We shall bring to each lonely life a smile,
But what have we brought today?
We shall give to truth a grander birth,
And to steadfast faith a deeper worth,
We shall feed the hungering souls of earth,
But whom have we fed today?

We shall reap such joys in the by and by,
But what have we sown today?
We shall build us mansions in the sky,
But what have we built today?
'Tis sweet in the idle dreams to bask,
But here and now do we do our task?
Yes, this is the thing our soul must ask,
"What have we done today."

—Woman's Life.

The Good Luck of Simon

"Hip, hip, hooray!" Simon bounded through the kitchen door as if shot from a catapult, and tossed his hat to the ceiling, while he cut several capers and flourishes across the cleanly scrubbed floor. His face was a shade redder than usual, and a scintillating light shone in his eyes.

"Why, what on earth is the matter?" cried Mrs. Thistledew, startled out of her usual serenity, by this crazed exhibition on the part of her husband.

"Hip, hip, I say! Toss up your bonnet! Throw up your feet, send every thing flying!" cried Simon again, suiting the action to the words.

Mrs. Thistledew backed into a corner and looked at him with terrified eyes. It had come, that which she had always feared—Simon was insane! Yes, note the fire in his eyes! What should she do.

"Simon, oh Simon!" she began.

"Don't oh, or Simon me! No more ohs or woes for us, Helen. We're in clover," and Simon made a dash for Mrs. Thistledew's corner, and catching her in his arms began to waltz about the room.

"Oh, do stop! What will the children think? Let me go, do let me go!" cried the good woman, her fright increasing at this further proof of Simon's insanity.

"Not a bit of it! We must celebrate our good fortune. Don't ever tell me I don't know what I'm about!" cried Simon. "Don't interfere with my bargains again! I'm a huckleberry, I am, and knwo a good thing when I see it." Simon swung his partner again off her feet, as he whirled about.

"I wish—wish—you'd tell me—what—what this means!" gasped Mrs. Thistledew, in breathless terror. "I think you're crazy—or—or—drunk."

"Ha, ha! Drunk am I? Well, I've reason to be drunk. Drunk with success. What about the twenty acres now, madam? What about my bad bargains? Can you tell me? Come, let's hear from the court!" and dropping his wife into a chair, Simon stepped opposite her and stuck his thumbs into the armholes of his vest with the assumption of a bank president.

The panting woman looked at him anxiously.

"I've been offered twelve hundred dollars for the timber on the twenty-acre lot! What do you think of that, Mrs. Thistledew? How does that strike your ladyship? Did I strike a bargain, or not? Say, was that a bargain day when I bought the Green lot? Hey? Well, I should remark. And you opposed my buying it."

"Twelve hundred dollars! Oh, Simon!" Mrs. Thistledew caught her breath. "It cannot be possible—"

"It can't, hey? That's all you know about it. It's ship timber, and there are a couple of fellows in town buying up all they can get of it."

"Of all things, Simon, how did such luck ever come to us? Now we can pay off the debt and have—the land to pay taxes on," she murmured.

"Pay taxes on? Great Scott! Ain't the land worth anything? Don't you consider land worth anything madam?" Simon was red in the face.

"Why, yes, Simon, of course. But you have so much more than you can work, and I was wishing they had bought the land, too. For if the timber is all off of it, you will have to plow it, will you not?"

"The ship timber isn't all there is on the land, Mrs. Thistledew. If it was all ship timber we would be rich. But there's plenty more, to use for other purposes. You are enough to put a man in an insane asylum. I wonder I am not more bald-headed than I am.

"Well, I'm glad you are going to get something off from the land. You'll surely sell the ship timber, Simon?" she continued, as the thought of a possible hitch in the arrangements occurred to her.

"Well," said Simon with an assumption of indifference, "that depends. I think I should have fifteen hundred, and if by waiting for other buyers—"

"Oh, don't do it, Simon! No others will come. They will learn that the timber has been bought up around here and will not come. I do hope you will close the bargain at once." Mrs. Thistledew wiped the perspiration, caused by her excitement, from

"For once, madam, you cannot quote to me 'Procrastination is the thief of time.' For once I've nabbed Old Time by the forelock. I've anticipated you. The timber is sold and I have the cash in my fist. Look at that will you? Isn't that a sight for a blind man?" Simon flourished a roll of bills before his wife's face.

Mrs. Thistledew felt as if the world was dropping out from beneath her feet. Could it be possible. Fortune had come their way at last and there was a prospect of being out of debt? She felt as if a ton's weight had been rolled from her shoulders. They had already paid two hundred dollars on the thousand the land cost them, and now they could pay the remainder and have four hundred dollars left. It seemed a fortune to her just then. Visions of house improvement flitted before her eyes. Some new back steps and a cistern were possibilities, and maybe she could have that which she had so long wanted—a sewing machine. She heaved a blissful sigh of relief, but before she could put her hopes into words, Simon continued:

"Yes, I calculate this is going to put us on our feet. I ordered a new reaper-and-binder, as I came through town and a sulky plow. There are some improvements on the binders that will save a heap of hard labor. These things cost like blazes, but they'll leave me enough to pay my taxes and then we can start square with the world. I feel all at once like a millionaire."

"Yes? But couldn't you get along—did you have to get the sulky plow?" Mrs. Thistledew faltered. "You've always plowed with the others."

"What if I have? Is that any reason I always must in the future? I'm not going to be dragged along over hubble and stubble at the handle of a plow when there's a chance to ride, I can tell you. I've had enough of it! A sulky plow is one of my luxuries, madam!"

"Oh!" It was all Mrs. Thistledew could ejaculate, but it was expressive. "What's the matter with you? You look as if you had lost your last friend, instead of being off your head with this streak of luck."

Mrs. Thistledew had risen and was poking the fire in the dilapidated old kitchen stove, preparatory to getting supper. She made no answer.

"Why, I verily beileve you are crying. What in the name of all creation is the matter? Is that your way of showing joy?" Thistledew looked disgusted.

"I am—very—very glad, Simon," she stammered, but—but the smoke got in my eyes from this smoking stove, that is all." And she crept softly out of the room and carefully down the rickety steps to bring in an armful of wood.—Rosetta Luce Gilchrist.

A HINT TO MOTHERS.

A business man pointing to a woman and a young girl who were going up the street chatting to each other, said to one of the scribes:

"Do you know that woman?"

"No."

"Well, ostensibly she is a lady. She knows how to appear well in public and has the entree of respectable homes. In reality, as some men about town well know, she is a depraved woman. But she dresses well and preserves appearances. She has not been ostracised because she is smart and discreet. She deceives the elect.

"And the young girl. She is evidently intimate with the woman. Probably she is a pure girl. She will not be so long. I wish I knew her father. I would like to warn him. Couldn't you put something in the paper about dangerous women of that kind?"

The conversation set the newspaper man to thinking.

Mothers warn their daughters against all evil-minded men but are they careful concerning evil-minded women?

A morally debased woman is ten-fold more dangerous to an innocent girl than a morally bad man.

A woman is able to get closer to the girl. From a sullied woman the girl will see only the alluring side of sin. She will hear nothing of the woes of transgression. She will not be warned of the awful decline and the wretched end. And so she is tempted, tainted, ruined.

The woman here referred to is not exactly a procuress. In effect that is what she is. She will hand over that girl to evil ways, she will damn the girl body and soul.

Mothers!

As you love your daughters know the sort of woman with whom your child is intimate—Examiner.

TEACHING USEFUL LESSONS.

This is a utilitarian age. There are many lessons to inculcate in the minds of the growing generation, among which none is more important than the all-absorbing one of economy.

"Waste not, want not," "Save the pennies and the dollars will take care of themselves," and a score of other old adages are given the young mind to train it in the way it should go.

There is another idea of as much importance as economy, and that is to make a proper distinction between economy and parsimony.

But while economy is a virtue, parsimony is a crime; and few parents draw a distinction between the two in talking to their children. I believe in saving a portion of one's earnings; I believe in keeping in advance of necessity, because it means usefulness instead of dependence; lifting instead of leaning; hopefulness instead of fear, in facing the future, says Ella Wheeler Wilcox. Continuing, she gives the following advice:

But of two misfortunes, I would rather see a child lean toward extravagance, if that extravagance were coupled with generosity, than toward a miserly tendency to accumulate and save.

Nothing dwarfs the whole nature more than parsimony. A young man whose leading thought is economy, and who counts every cent over and over with miserly care before indulging in a necessary expenditure or a

The Star Oil Burner

BURN AIR AND SAVE FUEL

You can do it with the

HAGUE IMPROVED DOMESTIC OIL BURNER

It burns more air than any other burner on the market. Can be fitted to stoves, ranges, furnaces, and all kinds of heating systems. Simplest and most economical burner on the market. If you want the most heat for the least money, write for information to

Hague Domestic Oil Burner Co., 810 So. Spring St., Los Angeles, Cal.

graceful courtesy toward a friend, is certain to grow narrow in his sympathies and prejudiced in his opinions, and, like a dwarfed, perverted vine tree, his tendrils will turn in and cling about himself instead of reaching out to adorn the world.

If you are just setting forth in life with an ambition to achieve, let generosity stand side by side with economy in your heart. If they are not there naturally, plant the seeds and water them well and expose the soil to the sun of love.

If you earn enough to save a few dollars a month out of your wages, don't spend it all, but make a rule of investing at least one dollar in some good cause for humanity. And do not forget, with every dollar so invested, add as interest your thought for the good the dollar may do. Do not give it to the first street beggar or the first professional letter writer who asks—that will be encouraging pauperism—but find some one more needy than yourself or more unfortunate, and plant your seed of generosity both for the sake of the one who will be benefited and for your own moral growth.

The opportunity to do a charitable act and thereby advance our own spiritual growth comes to every man and woman, and only as it is heeded, certainly does it add a gem in that crown of happiness which is free to all who court it.

Give something, a few pennies if no more, now and then, to aid the animal protective society and the humane educational organizations.

Children and animals never impose upon charity, and you may be sure whatever you do in their behalf is well bestowed.

Consider all such use of your small earnings as seed well planted. So surely as you cultivate this spirit of generosity and helpfulness so surely shall prosperity attend your efforts as the years pass, and so surely shall your enterprise meet with success.

THE PRETTY WOMAN.

Whatever philosophic advisers of the plain girl may say, personal attractiveness is almost an essential to a woman's success in life. We hear a great deal about the fascinating ugly girl, but we do not believe in her. "Goodness in woman, not her beauteous looks." No doubt, Mr. William Shakespeare! Goodness is, of course, a qualification which is indispensible to her, but it ought to be aided by beauty.

Why is it that since all ages woman's most fervent desire has been to have, and to retain, beauty? Because the heaven-sent instinct within her tells her that if she isn't pretty she will have a rather dull time of it in life! This is principally because the world and most things in it are—unjustly, most unjustly—in the hands of man, and of all things in this world the lords of creation like best a pretty woman. So where does the poor plain woman see her chance of success? She applies for a post of typewriter or secretary. She may be as learned as Minerva, as efficient as the head mistress of a county council school, as accurate as the gramophone, or possess all the other business qualifications under the sun, but if she is plain, that is to say, indubitably plain of face and figure, the would-be employer says, "Hum! Call again and we will consider it." Then he straightway engages the first pretty applicant! Probably the employer in question may not say two words a day outside business topics to the girl, but he objects strongly, that is all, to the presence of plainness.

Engage a nurse for your cherished infant. That cherished but misguided infant will turn scornfully from the homely, capable young woman who would encompass his youthful hours with comfort, and cry for the rosy-cheeked, blue-eyed maid who is probably most incapable, but who will amuse him and please his critical eye for the artistic. Your little boy will plead for a pretty governess, though your little girl, with more shrewdness, will perceive the beauty of goodness in the plainer face of another teacher. It is the pretty woman who gets all the burdens carried for her, doors opened for her, and her comforts considered, and is waited on asiduously by willing cavaliers—all for the reward of a smile and a brief word of thanks from the lips of beauty.

It is all very well to say it is charm of manner that counts, but charm of face is much more potent. A beautiful woman finds forgiveness where the plain woman may plead in vain, and what we term in the latter "shocking manners," we often call "originality" in the former. The pretty girl should see to it that she does not take undue advantage of her enviable position, for there are bounds beyond which even the most beautiful may not go. To apply the moral still further—beauty of person will fade, and the pretty woman who depends on her charm of face, will find herself bankrupt one day if she does not provide for the future of her popularity in some other ways.—Melbourne Leader.

THRIFT OUR SECOND NATURE.

How people can manage to look well in time-worn clothes is aptly told by a writer in the Farmers' Sentinel. The application can be made to every home in California no matter if the occupants are poor in this world's goods.

The writer entitles her article, "Mistaken Opinions of Frugality."

"She must have been poor," said a woman who had just returned from Europe, and was speaking of a lace-maker of Paris whom she had seen at work in her tiny apartment, "but there were no evidences of misery in sight."

The above remark, made not long since in my hearing, at once set me to thinking. Why was the idea of certain misery implied? Because the lace-maker lived in an humble way, of course. Had she hung out a gilt shingle before a glittering shop somewhere in the gay French capital, she would have presented a prosperous front to the world, even though it might have been that her rent was in arrears, and the clothes upon her back unpaid for.

It is barely possible that our ideas upon the condition resulting from the necessity of care in the management of household expenses need a little revision, if not a thorough overhauling. Few people are poor from choice. Most of us would enjoy absolute freedom from anxiety about money matters; there is not a doubt of it; but that misery is bound to accompany habits of thrift and economy does not by any means follow. The most independent person on earth and the happiest is he who has the sense to use his money in the right way. No starting at the ring of the doorbell for him; no dodging across the street to escape the demands of importunate creditors; no stammering excuses to collectors about bills that can never be paid. The softest pillow ever made is the one that supports the head of the provident man or woman. It contains no thorns, has not even the sharp end of a feather to arouse us to a sense of trouble and concealment. There is no trouble or concealment. Do we wear shabby clothes? Well they are paid for. Wasn't Dr. Johnson who went about with shabby elbows of a coat "all his own," in contrast to Goldsmith, who sported blue velvet suits for which he never paid? Perhaps our table lacks delicacies, but it holds enough of the plain substantial food that nourishes a healthy body, and with this we must be content until such time as fortune smiles again. And if it should be that the dame steadfastly refuses to look pleasant, why, it will not matter much, for our thrift will have become second nature to us."

BUYING BY MAIL.

Editor Cultivator: I live in the country, ten miles from Riverside, I have been buying my goods of late by mail order. Goods are delivered the third day by R. F. D. I find I can do better in this way than to go to town twice a week, lose a day and come home tired out. It is convenient and saves time. I make payment at the end of the month, the bill for each order accompanying the package delivered. It is much simpler and takes much less time to write an order than to visit the store, and my orders are always filled very exactly and promptly. I have never yet had any unpleasantness with a clerk and find when clerks are treated as they should be, they are willing and anxious to please a customer no matter what the amount of the purchase.

I would like my farmer sisters to try the plan. I think they will like it.—M. E. L.,Corona.

USE OF HONEY IN COOKING.

Editor Cultivator: Please publish some receipts for use of honey in cooking or baking.—J. E. B., Escondido.

Strained honey is sometimes used for sweetening sauces, but not generally. There is the danger always that its flavor may attach to the article it is used with. Honey contains more saccarine matter than sugar and would have to be used in the proportion of molasses or syrup. Cook books do not contain any well authenticated rules for the proportionate amount of honey as compared with sugar. So we can not give definite rules for its use. Be governed by taste when using it.

Cookery Recipes

Corn Bread.—This is particularly choice when made with sour cream. Mix and sift together one and one-half cups of corn meal, one-half cup of flour, one teaspoon of salt, one tablespoon of sugar and one-half teaspoon of soda. Beat an egg, add a cup of thick sour cream and pour gradually into the dry ingredients. Beat thoroughly, add cold water or a little more cream if necessary to thin the mixture slightly. Pour into a hot, well-buttered pan and bake from twenty to thirty minute in a moderate oven. Bake in gem pans for muffins.

* * *

Quince Marmalades.—Pare and quarter and core the quinces; and cook the cores one hour, strain the juice through a strong jelly bag to extract all the gelatineous substance. The quinces should in the meantime, have been covered with cold water. Drain the fruit on a cloth, add the juice, mash through a coarse collander, add the heated sugar, and cook about 15 minutes, or until thick and smooth.

* * *

To Prevent Burning.—If several large new marbles are dropped into the kettle where fruit is cooking, they will prevent burning on the bottom, the marbles being kept in motion by the boiling. Try it when making apple butter, marmalade or catsup, requiring constant stirring.
